Amnesic disorders are multifaceted conditions, with respect to etiology, course, and prognosis. Herein, data on epidemiology, clinical and neuropsychological aspects, and neurobiology and neuroimaging of amnesia due to psychological mechanisms (psychogenic, dissociative, or functional amnesia) are reviewed. By emphasizing the commonalities and dissimilarities between 'psychogenic' and 'organic' amnesia, biopsychosocial models of illness and a common intellectual approach to both neurological and psychiatric diseases are endorsed.

Amnesic disorders have as signature characteristic a severe memory impairment (*see* Amnesia: General), which occurs in a responsive, alert individual, in the absence of other significant cognitive impairments (Markowitsch and Staniloiu, 2012a). They are multifaceted conditions, with various causes, presentations, and prognoses, being differentiated into acute and transient, and chronic (lasting for more than a month). The inability to consciously acquire new information for long-term storage was named anterograde amnesia, and the inability to consciously recall previously stored information was designated retrograde amnesia. The memory impairment in amnesic disorders is frequently selective with respect to content-based categorizations of long-term memory (Markowitsch and Staniloiu, 2012a). Often, the memory impairment exclusively or predominantly involves the episodic-autobiographical memory domain (*see* Episodic Memory). According to their preponderant etiological link, amnesic disorders are viewed as being due to a general medical condition, direct effects of substance use (persisting beyond the period of intoxication and withdrawal) or psychological mechanisms (dissociative amnesia), or as having a mixed or iatrogenic etiology.

The Thesaurus of Amnesic Disorders due to Prevailing Psychological Mechanisms

The group of amnesic disorders due to prevailing psychological mechanisms has over the years been captured by several constructs, such as hysterical, functional, psychogenic, dissociative, or medically unexplained amnesia, or mnestic block syndrome. In present international nosologies, dissociative amnesia and fugue replaced previous diagnostic entities of psychogenic amnesia and fugue, respectively (Spiegel et al., 2011). Being listed under the category of dissociative disorders, dissociative amnesia and its variant dissociative fugue are considered to be causally bound to psychological stress or trauma. They are regarded as having as grounds the psychological mechanism of dissociation, where the latter represents a disruption or failure of integration of otherwise integrated aspects of cognition (memory), perception, identity, consciousness, and emotion (Janet, 1907; Spiegel et al., 2011). Some authors submitted to criticism the construct 'dissociative amnesia' due to its peremptory theoretical load, favoring the use of other terms (McKay and Kopelman, 2009). The term psychogenic amnesia has subsequently survived in the literature, designating amnesic disorders due to various psychological mechanisms, including dissociation. The terminology 'functional amnesia' initially indicated the opposite of organic amnesia. It was then applied to amnesic conditions that occurred without evidence of significant brain damage and had unclear etiology (de Renzi et al., 1997). When brain damage was identified in functional amnesia by conventional structural imaging methods, the locus and/or severity of brain damage did not typically match the nature and extent of memory impairment (disproportionate amnesia) (Markowitsch and Staniloiu, 2013).

Despite some debates, several writers have used the terms psychogenic, dissociative, and functional amnesias interchangeably, implicitly acknowledging in this manner that many functional amnesias have a psychological mechanism (Fujiwara et al., 2008; Kritchevsky et al., 2004; Markowitsch and Staniloiu, 2013). The lack of readily identifiable psychological factors in some cases of functional amnesia was conjectured to have arisen from the amnesia itself (in functional retrograde amnesia), an impaired capacity for emotional awareness and clarity or the incubation effect of trauma (Markowitsch and Staniloiu, 2013). As opposed to other terms used for describing amnesic disorders due to prevailing psychological mechanisms, the term functional is regarded as possessing several advantages, which may explain a rejuvenated interest in it (Stone, 2009; Markowitsch and Staniloiu, 2013). These include circumventing the mind-brain debate and emphasizing the functional aspect of the illness for the patient (the flight into illness and potential gain from illness; Markowitsch and Staniloiu, 2013). Furthermore, the word functional may map onto the concept of dynamic lesion, which had been described by Charcot (see Markowitsch and Staniloiu, 2013) and has received support from functional imaging studies (Brand et al., 2009).

The construct 'mnestic block syndrome' was coined by Hans Markowitsch to name a form of retrograde (autobiographical) amnesia, without referring to a clear causation, but highlighting the role of massive or long-lasting stress or trauma in the development of the amnesic condition in these patients (e.g., Markowitsch, 1996, 1997, 1998, 2000, 2003; Markowitsch et al., 1999b, 2000; Brand and Markowitsch, 2009). While avoiding the mind-brain dispute, the construct 'mnestic block syndrome' alludes to mechanisms that are purported to be involved in this condition. The memories are not lost. Only the access to the memories is blocked throughout the period of the illness (Markowitsch, 1996; Spiegel et al., 2011). Similar to the expression 'functional amnesia', the term 'mnestic block syndrome' conveys hope for recovery or improvement (Stone, 2009).

Types of Functional or Psychogenic Amnesia

Functional amnesias are heterogeneous conditions, which could be triggered by psychological factors or a combination of psychological and somatic factors. The physical factors implicated in precipitating functional amnesias are usually of mild intensity (mild traumatic brain injury or mild electrocuting accident). Cases of functional amnesia, however, might also arise after more severe brain insults (Kopelman, 2000; Pommerenke et al., 2012; Fast and Fujiwara, 2001). However, in the presence of significant brain pathology (as detected by conventional brain imaging), the psychological factors contributing to the amnesic condition are more likely to be discounted or neglected and subsequently the condition may solely be attributed to an 'organic' cause (Kopelman, 2000).

Sometimes, functional amnesias occur suddenly after a massive psychological trauma; at other times there may be a period of lag between the psychologically traumatic incident and the onset of amnesia. Not uncommonly, functional amnesia was reported to occur after a seemingly objective minor incident; however, in most cases, a careful anamnesis unearthed a history of recurrent psychologically stressful or traumatic experiences, often with onset in childhood or early adulthood.

Functional amnesias can be classified into acute and chronic. Amnesias persisting over a month period were deemed chronic. This duration cutoff for chronicity may have stemmed from older studies, which showed that a high percentage of psychogenic amnesias recovered within a month from their onset (Abeles and Schilder, 1935). Traditionally, functional amnesias were viewed as being preponderantly acute and transient in many countries outside of the North America (Spiegel et al., 2011). For the last two decades, several authors, however, described a chronic course of memory impairments in a substantial number of patients with functional or psychogenic amnesia (Fujiwara et al., 2008; Staniloiu and Markowitsch, 2012; Hennig-Fast et al., 2008). The conflicting findings with respect to the course of amnesia may be accounted for by several factors, such as the referral bias and the progress made in the conceptualization of episodic-autobiographical memory and the development of neuropsychological methods for detecting memory impairments (Kritchevsky et al., 2004; Markowitsch and Staniloiu, 2013).

Epidemiological and Demographic Data

Epidemiological data about psychogenic or functional amnesia are still limited. The prevalence values for dissociative amnesia were recently stated to range between 1.8 and 7.3% (Spiegel et al., 2011). Johnson et al. (2006) reported for dissociative amnesia a 12-month prevalence of 1.8% in a US community of 658 adults who were evaluated with psychiatric interview. Sar et al. (2007) conducted a study in Turkey where 43 of the 97 consecutive outpatients admitted to the psychiatric emergency department were initially screened for dissociative experiences using the screening tool Dissociative Experiences Scale (DES). The patients who had a DES score higher than 25 (39.5% of 43 assessed) were further evaluated with the Dissociative Disorders Interview Schedule and then the Structured Clinical Interview for Dissociative Disorders (the gold standard diagnostic instrument for dissociative disorders). Seven percent (3 patients) of the 43 patients met diagnostic criteria for dissociative amnesia. The average DES score of patients who met criteria for dissociative disorders was reported to be 43.7.

These above-mentioned data pose a challenge to older views of dissociative amnesia as being extremely rare, and subsequently draw attention to the risk of underdiagnosing or misdiagnosing this condition (Spiegel, 2006). Coons and Milstein (1992) had remarked that psychogenic amnesia may be missed when subtler clinical pictures are present or when other primary psychiatric conditions coexist. Furthermore, the explicit emphasis that the ICD-10 (1992) lays on the requirement to find 'convincing associations in time' between the symptoms of the dissociative amnesia and 'stressful events, problems, or needs' may lead some rushed clinicians or researchers to erroneously drop this condition into other diagnostic categories. As Kopelman (2000) noted, the uncovering of precipitating psychological factors in cases of amnesia is not always simple (Markowitsch et al., 1993). Furthermore, "sometimes patients will not allow you to know what had been happening, or they may disappear before you find out" (Kopelman, 2000: p. 612).

Psychogenic amnesia is most commonly diagnosed between ages 20 and 40 years (Coons and Milestein, 1992; Maldonado and Spiegel, 2008; Reinhold and Markowitsch, 2007), as opposed to transient global amnesia that tends to affect older individuals (*see* Transient Global Amnesia). In the sample of Coons and Milestein (1992), the age of patients with psychogenic amnesia ranged from 17 to 51 years. In the case series of Brand et al. (2009), the age of patients with dissociative amnesia ranged from 23 to 54 years. Several possible explanations for the clustering of cases of dissociative amnesia in the young adult segment were put forth (Staniliou and Markowitsch, 2012). Negative correlations were found between age and dissociation scale scores (Putnam, 1997). New research data suggested that mechanisms that capitalize on memory suppression become more taxing (demanding) with age (Anderson et al., 2011).

Furthermore, massive acute stress may have a differentiated effect on retrieval according to age (Pulopulos et al., 2013).

An underestimation of newly occurring, persisting, or recurring psychogenic amnesias in older age, due to a tendency in medical and psychiatric field to attribute cognitive symptoms in older patients to medical or more common psychiatric conditions cannot, however, be excluded (Kluft, 2007).

The sex ratio in dissociative amnesia was reported to be roughly one (Maldonado and Spiegel, 2008). Some studies, however, described a higher frequency of psychogenic amnesia in women (Coons and Milestein, 1992), and others in men (Kanzer, 1939; Kritchevsky et al., 2004; Brand et al., 2009). Some authors suggested that dissociative amnesia and other dissociative disorders may be underestimated in men (Spitzer and Freyberger, 2008). The mean educational level of patients with psychogenic amnesia reported by Coons and Milestein was 12.7 years; the years of education, however, ranged from 9 to 18 years (Coons and Milestein, 1992). These findings are consistent with results from other studies (Brand et al., 2009; Kritchevsky et al., 2004).

Psychogenic amnesias might recur. Coons and Milstein (1992) found that 40% of their sample had recurrent episodes of psychogenic amnesia. Abeles and Schilder (1935) reported a recurrent rate of 24%. Coons and Milstein (1992) attributed the elevated rate of recurrence in their sample to the features of their assessing setting (a tertiary care unit).

Risk Factors and Comorbidity

A previous history of psychiatric difficulties may be indicative of psychogenic or functional amnesia (Kritchevsky et al., 2004), although it was not unanimously reported (de Renzi et al., 1997). Coons and Milestein (1992) reported a high number of comorbidities with affective disorders, anxiety disorders, substance abuse, somatoform disorders, personality disorders, and other dissociative disorders among the 25 patients with psychogenic amnesia they had investigated in a tertiary care setting. As Spiegel et al. (2011) remarked, this high comorbidity rate might have reflected the severity and complexity of their clinical cases, who required referral to tertiary care clinic. Incidentally, this elevated comorbidity rate was not found in the case series described by Brand and colleagues (2009).

The Neuropsychology of Psychogenic Amnesia

On neuropsychological examination, patients with psychogenic amnesia often present with impairments of episodic-autobiographical memory, which are of retrograde nature (Markowitsch et al., 1997a). The episodic-autobiographical memory impairment can be restricted to a specific period of time or could span the entire life, or can be material specific. In comparison to the symptom of amnesia that may occur in posttraumatic stress disorder, the memory impairment in functional amnesia is usually more extensive, encompassing larger periods (Spiegel et al., 2011). With respect to semantic knowledge, autobiographical-semantic knowledge may initially be impaired (e.g., in psychogenic or dissociative fugue), but then it is relatively quickly relearned. In dissociative fugues, retrograde amnesia and personality loss are accompanied by sudden traveling from the customary environment (Markowitsch et al., 1997b). Albeit dissociative fugue currently is considered a separate diagnostic entity, several clinical, neuropsychological, and neuroimaging studies support its reclassification as a variant of dissociative amnesia (Spiegel et al., 2011; Staniloiu and Markowitsch, 2010; Markowitsch et al., 1997a,b; Hennig-Fast et al., 2008). Old general world knowledge is typically preserved in functional amnesia, but in some cases it may be affected in variable degrees (Brand et al., 2009; Kopelman, 2000; Kritchevsky et al., 2004). Priming is usually spared (Staniloiu and Markowitsch, 2012b). A limited number of studies of patients with functional amnesia provided objective evidence for impairments of previously learned procedural skills or for deficits in acquiring new procedural skills. Given that many patients quickly relearn their skills, their initial complaints might reflect a deficit in the 'procedural discourse' due to impairments in the semantic memory domain (Markowitsch and Staniloiu, 2013). In other cases, the 'loss' of skills may just represent difficulties with initiating or carrying out a task, either due to emotional-motivational factors or executive dysfunctions (Smith et al., 2010). Executive functions have been reported to be affected in a substantial number of patients with functional amnesia (Fujiwara et al., 2008; Brand et al., 2009).

Variable degrees of anterograde amnesia (which are detected by standard anterograde memory tests) can accompany retrograde forms of functional amnesia (Brand et al., 2009; Kopelman, 2000; Kritchevsky et al., 2004; Fujiwara et al., 2008). In patients with dense functional retrograde amnesia, the consciously acquired new memories for long-term storage are qualitatively different, in particular with respect to emotional flavoring and first-person autonoetic connection in comparison to memories of normal, matched participants. These qualitative changes may not be documented as they usually escape capturing on testing with standard anterograde memory tests. Functional anterograde amnesia in the absence of significant retrograde memory impairments or that is out of proportion in comparison to retrograde memory impairments can also occur, albeit it was much more rarely reported (Markowitsch et al., 1999a; Smith et al., 2010; Markowitsch and Staniloiu, 2013).

Several changes in personality dimensions were reported to have occurred after the onset of psychogenic or functional amnesia. These changes involved affectivity, perception (e.g., impaired self-face or face-emotion processing), cognition (e.g., social cognition), and behavior (e.g., changing in eating, smoking, drinking, or working habits) (for a review see Markowitsch and Staniloiu, 2013). Anomalous self-face processing was described in some cases (Pommerenke et al., 2012; Markowitsch and Staniloiu, 2013) and linked to a right-hemisphere dysfunction.

Pathogenetic Models of Psychogenic Amnesia

Two main models (that are not mutually exclusive) were espoused to account for the pathogeny of psychogenic

amnesia. Based on his clinical and neuroimaging findings, Markowitsch developed a model of functional amnesia that postulates that the memory impairment in the episodic-autobiographical domain in functional retrograde amnesia preponderantly reflects a stress hormone-mediated memory blockade ('mnestic block syndrome') (Markowitsch, 1998). This mnestic block syndrome is supposedly underlain by a right-hemispheric synchronization anomaly during retrieval attempts between the frontal lobe regions – important for autonoetic consciousness, search initiation and monitoring, and the temporoamygdalar system – important for emotional processing and appraising the self-relevance of social and biological stimuli (Markowitsch and Staniloiu, 2013). This memory impairment is opined to be triggered by adverse life conditions, usually of a recurrent nature and with onset in childhood or early adulthood; it is modulated by several factors, such as genes; personality characteristics; early parent–child attachment style; medical and psychiatric comorbidities; familial, ecological, and sociocultural environment; and epigenetic factors (Dalenberg et al., 2012). Changes in environment (especially these occurring in early life) were hypothesized to lead to genomic adaptations with consequences for stress hormonal response pattern, brain synaptic plasticity, and processing of incoming information (Markowitsch, 2003). Several key brain structures for autobiographical memory and emotional processing have been identified as being sensitive to the consequences of exposure to stressful experiences (such as amygdala and hippocampal formation, prefrontal cortex, and specific white matter tracts). Massive and prolonged stress might induce changes in regions with a high density of glucocorticoid receptors such as the anterior and medial temporal lobe. In animals, it was shown that stress enhances hippocampal long-term depression and blocks long-term potentiation. The effects of stress on the above-mentioned brain structures depend on their vulnerability, the magnitude of the neurotoxic (glucocorticoid) (*see* Hypothalamic-Pituitary-Adrenal Axis, Psychobiology of) cascade, and the stage of development of respective structures (Lupien et al., 2009). The hypothesis that increased glucocorticoid levels play a significant role in the mnestic blockade has received empirical support from several studies (for a review, see de Kloet and Rinne, 2007). The right-hemispheric synchronization defect during retrieval attempts in functional or dissociative amnesia was suggested by a number of functional neuroimaging studies (Brand et al., 2009; Markowitsch et al., 1997b) (*see* Functional Brain Imaging of Language Processes).

The other model that dominates the understanding of the pathogeny of functional amnesia posits that the inability to retrieve personal events in psychogenic amnesia results from an increase in the activity of inhibitory regions of the prefrontal cortex coupled with a subsequent decrease in the activity of the hippocampus, similar to the one that occurs in motivated forgetting (Kopelman, 2000; Anderson and Green, 2001; Anderson et al., 2011). In line with this model, Fujiwara and Markowitsch (2003) argued that the executive control – or supervisory attentional system – is engaged in holding undesired or distressful memories out of self-awareness or autonoetic consciousness (*see* The Neural Basis of Consciousness). This may result in an overload of the executive system and may reduce the frontal cortex-associated cognitive reserve that is necessary for successful retrieval of other nontraumatic or nonstressful personal memories in functional amnesia. In agreement with this model are findings suggesting that executive functions may covary with successful retrieval of autobiographical memory (Brand et al., 2009). In the study of Brand et al. (2009), executive dysfunctions were found in four patients. These patients showed more extensive retrograde memory impairments than those with normal performance on executive function tests.

The Neuroimaging of Psychogenic or Functional Amnesia

Neuroanatomical, neuropathological, and neuroimaging studies of amnesic disorders had in the past promoted sharp distinctions between amnesias with evidence of brain damage ('organic') and amnesias without (overt) evidence of brain damage('functional'). Case reports and group studies of neurological patients delivered evidence of amnesia arising after (usually bilateral) damage of the regions in the limbic system (*see* Limbic System), partitioned into the medial temporal lobe (*see* Hippocampus and Related Structures; Temporal Lobe), the medial diencephalon (*see* Hypothalamus), and the basal forebrain. Since the advent of functional imaging (*see* Functional Brain Imaging of Language Processes) and wider utilization of structural imaging methods, such as diffusion tensor imaging, several studies have been providing evidence in functional, psychogenic, and dissociative amnesia of metabolic or microstructural changes of brain areas that are presently agreed upon to be crucially implicated in conscious mnemonic processing (*see* Consciousness, Neural Basis of); these findings have subsequently been challenging the perceived gap between 'functional' and 'organic' forms of amnesia (Staniloiu and Markowitsch, 2010).

Markowitsch et al. (1997b) investigated a 37-year-old man with persistent retrograde memory impairments after an episode of dissociative fugue. The patient remained unsure of his relationship to family members and changed a number of personality traits. While having been an avid car driver prior to the fugue, he became quite hesitant to enter a car thereafter, lost his asthma and allergies, gained a substantial amount of weight and changed his profession. Regional cerebral blood flow was estimated with water positron emission tomography (PET) during an autobiographical memory paradigm; it revealed a preponderantly left-hemispheric activation instead of the usual right-hemispheric frontotemporal one found with the same paradigm in normal participants. This result suggested that the patient indeed might have been unable to recollect his own past and instead processed this information as new and unrelated to his person (in a semantic, factual way, without the feeling of warmth and without the first-person autonoetic connection, which accompanies a recollecting experience). Related to this finding, another functional imaging technique (single-photon emission computed tomog

raphy) revealed in another patient with psychogenic amnesia a hypometabolic zone in exactly that frontotemporal junction area, which is necessary for normal retrieval of autobiographical memories (Markowitsch et al., 1997a). A similar hypometabolic zone in the same brain region was detected after organic brain damage and retrograde amnesia (Calabrese et al., 1996). These findings suggested that there may be a block or disconnection of memory-processing neural nets, leading to both 'psychogenic' and 'organic' amnesia (Markowitsch, 1999).

In a subsequent study in which glucose-PET data obtained at rest from 14 patients with dissociative amnesia and severe retrograde episodic-autobiographical memory impairments were analyzed, it was found that the right temporofrontal region was hypometabolic in a significant number of patients, with a significant reduction in the right inferolateral prefrontal cortex (Brand et al., 2009) (**Figure 1**). A reinforcement of these results came in the same year from the work of Tramoni et al. (2009), who in a patient with functional retrograde amnesia performed magnetization transfer ratio measurement and magnetic resonance spectroscopic imaging and found evidence of significant metabolic and subtle structural changes within the white matter of the right prefrontal region. These results lend support to previous proposals that the functional amnesic conditions might be underlain by a disconnection syndrome.

With respect to the neural correlates of the functional anterograde amnesia, neuroimaging data are sparse and inconclusive (Smith et al., 2010). Markowitsch et al. (2000) described a patient who developed both retrograde and anterograde amnesia after witnessing an open fire in his house. The retrograde amnesia spanned the last 6 years of his life. When investigated with glucose-PET, the patient displayed an overall reduction in his regional glucose metabolism in the cerebrum, with an even greater reduction in medial temporal and diencephalic regions. The hippocampal formation (*see* Hippocampus and Related Structures; Temporal Lobe) was found to be bilaterally hypometabolic. A metabolism of three standard deviations below that of normals was found in his right temporobasal, left temporomesial, left and right frontobasal, left insular, and dorsoparietal cortex. A metabolism of two standard deviations below normal was found in the left temporobasal, the right and left frontomesial, the right insular, the left cerebellum, and the left putamen. His reduced glucose metabolism corresponded to that of a patient of similar age and same sex, who after a major heart attack displayed the same type and extent of glucose reduction in his brain (Markowitsch et al., 1997b). The patient's amnesic condition persisted for several months but improved thereafter. The improvement in his conscious mnemonic abilities occurred in the context of combined psychotherapeutic and psychotropic treatment and was paralleled by a normalization of his glucose metabolism in the cerebrum.

The Differential Diagnosis of Psychogenic Amnesia

Similar to the transient global amnesia (*see* Transient Global Amnesia), functional amnesias can be triggered by a mixture of psychological and physical factors (Quinette et al., 2006). There are several important features that distinguish functional or psychogenic amnesia from transient global amnesia (cf **Table 1**).

The main challenge posed by the differential diagnosis of psychogenic (dissociative) amnesia is distinguishing between true and feigned amnesia (Barbarotto et al., 1996). In some cases, the preserved ability to retrieve information via other memory systems than the episodic-autobiographical memory system may lead clinicians to conclude that an individual is feigning amnesia. In other cases, there may be a mixture of true amnesia and feigning/malingering, making for a difficult diagnosis (Spiegel et al., 2011).

Treatment, Course, and Prognosis of Psychogenic Amnesia

Functional amnesias differ greatly with respect to recovery; variables that may independently predict prognosis are, however, largely unknown. There is currently a dearth of knowledge about evidence-based treatments for these conditions (Markowitsch and Staniloiu, 2013). Data on neuropsychological rehabilitation for psychogenic amnesia are sparse (Markowitsch and Staniloiu, 2012b). Furthermore, there is a stringent need for developing a broad theoretical framework for rehabilitation (Wilson, 2008) of psychogenic or functional amnesia and adopting a holistic approach that should aim toward achieving optimal 'physical, psychological, social, and vocational well-being.'

Conclusions

The possibility that both somatic and psychological factors make contributions to the clinical picture of various amnesic disorders had been emphasized by Mai's (1995) statement that "the presence of a neurological abnormality does not necessarily rule out psychogenic amnesia" (p. 105). After the legitimization of the transient global amnesia (Fisher and Adams, 1964) as a diagnostic neurological entity, several cases of psychogenic amnesia were recategorized as representing instantiations of transient global amnesia (de Renzi et al., 1997) (cf **Table 1**). Over half a century later, psychological factors are reacknowledged as being potentially involved of transient global amnesia (TGA) symptomatology (Quinette et al., 2006) (cf **Table 1**). Furthermore, functional neuroimaging data point to neural correlates of functional or psychogenic amnesias. These on the one hand challenge the deeply seated organic–psychogenic dichotomy. On the other hand, they open a pathway of hope for the development of effective treatments and comprehensive models of rehabilitation (Wilson, 2002) for these conditions and call for larger scale studies that use increased methodological rigor, combined neuroimaging methods, and rejuvenated research framework. As Markowitsch stated in 1999, "A common framework for psychiatry and neurosciences emphasized 115 [years] ago by Meynert who attempted to explain all psychic functions by anatomy and physiology […], is nevertheless a central aim for … the next century […]" (p. 335).

Figure 1 Relative decreases in regional cerebral glucose metabolism in 14 patients with dissociative amnesia relative to 19 control subjects (sagittal, frontal, and horizontal views as 'glass brains' and superimposed on magnetic resonance imaging (MRI) sections, MRI template). The cross indicates the locus of the only significant deactivated spot in the right inferolateral prefrontal cortex ($P_{corrected} < 0.001$, $x =$ "6 mm, $y = 24$ mm, $z = -14$ mm). The homologous hypometabolic region within the left inferolateral prefrontal cortex failed to reach significance ($P_{corrected} < 0.083$, $x = -22$ mm, $y = 24$ mm, $z = -14$ mm). Reproduced from Figure 1 of Brand, M., Eggers, C., Reinhold, N., Fujiwara, E., Kessler, J., Heiss, W.-D., Markowitsch, H.J., 2009. Functional brain imaging in fourteen patients with dissociative amnesia reveals right inferolateral prefrontal hypometabolism. Psychiatry Research: Neuroimaging Section 174, 32–39.

Table 1 General forms of amnesic states and their behavioral characteristics

Type	*Transient global amnesia*	*Functional (psychogenic) amnesia*
Typical age at the time of diagnosis	50–70 Years	20–40 Years
Precipitating factors	Strenuous physical activity or emotional stress or a combination of physical and somatic factors	Psychological stress or a combination of psychological and somatic factors
Occurrence	Suddenly, frequently after significant physical or psychic incidents	Suddenly, either after chronic stress or after a single major stressful incident
Duration	$\leq$24 h	Variable
Affected memory systems	Mainly episodic-autobiographical	Mainly episodic-autobiographical
Loss of personal identity	No	Frequent
Affected time range	Anterograde and variable retrograde	Retrograde and/or (more rarely) anterograde
Patient's behavior	Temporal disorientation, iterative questioning, concern about his/her condition	Often presenting with la belle indifference
Remission/recovery	Usually complete, but mild impairments in episodic memory may persist several months after the remission of the core amnesic syndrome	Sometimes complete, sometimes persistent
Brain changes	CA1 field of hippocampal formation	Prefrontal and limbic regions Fibers projecting to prefrontal cortex

Abstract

Analysis of variance (ANOVA) models apply to data that occur in groups. The fundamental ANOVA model is the one-way model that specifies a common mean value for the observations in a group. The ANOVA associated with the one-way model is presented. When the groups in a one-way ANOVA are identified as combinations of two or more factors, models incorporating factor main effects and factor interactions provide a useful device for exploring the underlying structure of the data. The main effects only two-way ANOVA model is discussed along with its interpretation and how it differs from the interaction model. Three-factor models and their interpretations are discussed. Appropriate models can be identified by fitting sequences of successively smaller models and using general testing procedures to identify models within each sequence that fit well. ANOVA models are also useful in generalized linear models. These are discussed with examples involving logistic regression. Again, appropriate models can be identified by fitting sequences of models.

Analysis of variance (ANOVA) models are models that exploit the grouping structure in a set of data and lend themselves to the examination of main effects and interactions. These models are often referred to as being hierarchical in that it makes no sense to test whether main effects can be dropped from a model that includes that factor in an interaction, and it makes no sense to test whether a lower-order interaction can be dropped from a model that includes any higher-order interaction involving all of the same factors. The modeling ideas also extend to generalized linear models (GLIMs).

One-way ANOVA

One-way ANOVA models identify groups of observations using a separate mean for each group. For example, the observations can be the age of suicide categorized by mutually exclusive ethnic groups. Suppose there are a groups with N_i observations in each group. The jth observation in the ith group is written y_{ij} with expected value $\mathrm{E}(y_{ij}) = \mu_i$. The one-way ANOVA model is

$$y_{ij} = \mu_i + \varepsilon_{ij} \qquad [1]$$

$i = 1, \ldots, a$, $j = 1, \ldots, N_i$ where the ε_{ij}s are unobservable random errors with mean 0, often assumed to be independent, normally distributed with variance σ^2, written $\varepsilon_{ij} \sim N(0, \sigma^2)$.

The ANOVA is a procedure for testing whether the groups have the same mean values μ_i. It involves obtaining two statistics. First, the mean squared error (*MSE*) is an estimate of the variance σ^2 of the individual observations. Second, the mean squared groups (*MSGrps*) is an estimate of σ^2 when the means μ_i are all the same and an estimate of σ^2 plus a positive number when the μ_i are different. The ratio of these two statistics, *MSGrps/MSE* should be approximately 1 if the μ_is are all the same and tends to be larger than 1 if the μ_is are not all the same. Under the normality assumptions for the ε_{ij}s, when the μ_is are all the same the exact value of *MSGrps/MSE* is random and follows an F distribution with $a-1$ degrees of freedom in the numerator and $n-a$ degrees of freedom in the denominator. Here $n = N_1 + \ldots + N_a$ is the total number of observations in the data. If the observed value of *MSGrps/MSE* is so much larger than 1 as to be relatively inconsistent with it coming from the F distribution, one concludes that the μ_is must not all be the same.

In the special balanced case where $N_i = N$ for all i, the computations are particularly intuitive as analyzing variances. To find the *MSE*, simply find the sample variance within each group, i.e., compute the sample variance from $y_{i1}, \ldots, y_{iN}$, then average these a numbers to get *MSE*. This provides an estimate of σ^2. To get *MSGrps*, first compute the sample mean for each group, say y_i. Then compute the sample variance of the y_is and multiply by N to get *MSGrps*. *MSGrps* estimates $\sigma^2 + Ns^2\mu$ where s^2_μ is a new parameter consisting of the sample variance of the unknown parameters $\mu_1, \ldots, \mu_a$. The μ_is are all equal if and only if $s^2_\mu = 0$. *MSGrps/MSE* estimates $1 + Ns^2_\mu/\sigma^2$.

Terminology varies considerably for these concepts. The *MSE* is also called the mean squared residual and the mean squared within (groups). *MSGrps* is also called the mean squared treatments (because often the groups are identified as different treatments in an experiment) and the mean squared between (groups).

An alternative but equivalent model used with one-way ANOVA is

$$y_{ij} = \mu + \alpha_i + \varepsilon_{ij} \qquad [2]$$

$i = 1, \ldots, a$, $j = 1, \ldots, N_i$. Here μ is a grand mean and the α_is are differential effects for the groups. The problem with this model is that it is overparameterized, i.e., the μ and α_i parameters are not identifiable. Even if you know the μ_is, there is an infinite number of ways to define the μ and α_i parameters. In fact, you can arbitrarily pick a value for any one of the μ or α_i parameters and still make them agree with any set of μ_is. Without including extraneous side conditions that have nothing to do with the model, it is impossible to estimate any of the μ and α_i parameters. It is, however, possible to estimate some functions of them, like values $\mu + \alpha_i$, or contrasts among the α_is like $\alpha_1 - \alpha_2$. Linear functions of the μ and α_i parameters

for which linear unbiased estimates exist are called estimable functions. *see* Statistical Identification and Estimability.

The F test can also be viewed as testing the full one-way ANOVA model against the reduced model

$$y_{ij} = \mu_i + \varepsilon_{ij}$$

The reduced model can be viewed as either dropping the subscript i from μ_i in model [1] or as dropping the α_is from model [2]. In either case, the reduced model does not allow for separate group effects. The F statistic comes from the error terms of the two models

$$F = \frac{SSE(\text{Red.}) - SSE(\text{Full})}{dfE(\text{Red.}) - dfE(\text{Full})} \Big/ MSE(\text{Full}) = \frac{MSGrps}{MSE}$$

Extensions of ANOVA to more general situations depend crucially on the idea of testing full models against reduced models; *see* Linear Hypothesis.

Two-way ANOVA

Two-way ANOVA can be thought of as a special case of one-way ANOVA in which the groups have a two-factor structure that we want to exploit in the analysis. For example, Everitt (1977) discusses 97 ten-year-old school children who were cross-classified by two factors, first, the risk of their home environment: not at risk (N) or at risk (R), and then the adversity of their school conditions: low, medium, or high. This defines six groups, each a combination of a home environment and a school condition. To illustrate the modeling concepts, suppose the dependent variable y is the score on a test of verbal abilities. In general, we would write a model

$$y_{gk} = \mu_g + \varepsilon_{gk} \qquad [3]$$

where $g = 1, \ldots, G$ indicates the different groups and $k = 1, \ldots, N_g$ indicates the observations within the group. In the specific example, $G = 6$ and $(N_1, N_2, N_3, N_4, N_5, N_6) = (17, 8, 18, 42, 6, 6)$.

To use the two-factor structure, we begin by identifying the factors numerically. Let $i = 1, 2$ indicate home environment: not at risk ($i = 1$), at risk ($i = 2$). Let $j = 1, 2, 3$ identify school adversity: low ($j = 1$), medium ($j = 2$), high ($j = 3$). In general, let $i = 1, \ldots, a$ denote the levels of the first factor and $j = 1, \ldots, b$ denote levels of the second factor. Without changing anything of substance in the model, we can rewrite the ANOVA model [3] as

$$y_{ijk} = \mu_{ij} + \varepsilon_{ijk} \qquad [4]$$

$i = 1, \ldots, a$, $j = 1, \ldots, b$, $k = 1, \ldots, N_{ij}$. All we have done is replace the single index for the groups g with two numbers ij that are used to identify the groups. This is still a one-way ANOVA model and can be used to generate an F test of whether all the μ_{ij}s are equal. In our example, $a = 2$, $b = 3$, and $(N_{11}, N_{21}, N_{12}, N_{22}, N_{13}, N_{23}) = (17, 8, 18, 42, 6, 6)$. Note that with a two-factor model the number of groups is $G = ab$ and $E(y_{ijk}) = \mu_{ij}$.

The one-way ANOVA model [4] is often rewritten in an overparameterized version that includes numerous unidentifiable parameters. The overparameterized model is called the two-way ANOVA with interaction model, and is written

$$y_{ijk} = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij} + \varepsilon_{ijk} \qquad [5]$$

Here μ is a grand mean, the α_is are differential effects for the first factor, the η_js are differential effects for the second factor, and the $(\alpha\eta)_{ij}$s are called interaction effects. In reality, all of the μ, α_i, and η_j parameters are extraneous. If we drop all of them, we get the model $y_{ijk} = (\alpha\eta)_{ij} + \varepsilon_{ijk}$, which is just the one-way ANOVA model [4] with the μ_{ij}s relabeled as $(\alpha\eta)_{ij}$s. In model [5], without the introduction of side conditions that have nothing to do with the model, it is impossible to estimate or conduct any test on any function of the parameters that does not involve the $(\alpha\eta)_{ij}$ parameters. Since main effect parameters are extraneous when interactions are in the model, computer programs that purport to give tests for main effects after fitting interactions are really testing some arcane function of the interaction parameters that is determined by a choice of side conditions used by the program.

The interesting aspect of the two-way ANOVA with interaction model is that it suggests looking at the two-way ANOVA without interaction model

$$y_{ijk} = \mu + \alpha_i + \eta_j + \varepsilon_{ijk} \qquad [6]$$

This model is not equivalent to the one-way ANOVA model, but it includes nontrivial group effects. It amounts to imposing a restriction on the μ_{ij}s that

$$\mu_{ij} = \mu + \alpha_i + \eta_j \qquad [7]$$

for some μ, α_is, and η_js. This indicates that the group effects μ_{ij} have a special structure in which the group effect is the sum of a grand mean and differential effects for each factor, hence model [6] is referred to as an additive model. The two-way ANOVA without interaction model is still overparameterized, so none of the individual parameters are estimable, but typically contrasts in the α_is and η_js are estimable as well as values $\mu + \alpha_i + \eta_j$.

To illustrate the modeling concepts, suppose that in our example the group means for the verbal test scores take the values shown in **Table 1**. These μ_{ij}s satisfy the additive model [7] so they do not display interaction. For example, take $\mu = 0$, $\alpha_1 = 110$, $\alpha_2 = 100$, $\eta_1 = 0$, $\eta_2 = -5$, $\eta_3 = -15$. Note that μ, the α_is, and the η_js are not identifiable (estimable) because there is more than one way to define them that is consistent with the μ_{ij}s. For example, we can alternatively take $\mu = 100$, $\alpha_1 = 5$, $\alpha_2 = -5$, $\eta_1 = 5$, $\eta_2 = 0$, $\eta_3 = -10$. However, identifiable functions of the parameters include $\mu + \alpha_i + \eta_j$, $\alpha_1 - \alpha_2$, $\eta_1 - \eta_3$, and $\eta_1 + \eta_2 - 2\eta_3$. Identifiable functions take on the same values for any valid choices of μ, the α_is, and the η_js. For example, the effect of changing from a not at risk home situation to an at risk home situation is a decrease of $\alpha_1 - \alpha_2 = 10$ points in mean verbal test score. Similarly, the effect of changing from a low school adversity situation to a high school

Table 1 Mean verbal test scores, additive model

		j (School)		
	μ_{ij}	*1 (Low)*	*2 (Medium)*	*3 (High)*
i (Home)	1 (*N*)	110	105	95
	2 (*R*)	100	95	85

adversity situation is a decrease of $\eta_1 - \eta_2 = 15$ points in mean verbal test score.

The beauty of the additive model [6] is that there is one number that describes the mean difference between students having not at risk home status and students having at risk home status. The difference is a drop of 10 points *regardless* of the school adversity status. This number can legitimately be described as the effect of going from not at risk to at risk. (Note that unless the students were assigned randomly to their home conditions, this does not imply that changing a student's status from at risk to not at risk will *cause*, on average, a 10 point gain.) Similarly, the effect of school adversity does not change with the home status. For example, going from low to high school adversity induces a 15 point drop regardless of whether the students are at risk or not at risk. Statistically, tests for main effects are tests of whether any of the α_is are different from each other and whether any of the η_js are different from each other, in other words whether the home statuses are actually associated with different mean verbal test scores and similarly for the school adversities.

The existence of interaction is simply any structure to the μ_{ij}s that cannot be written as $\eta_{ij} = \mu + \alpha_i + \eta_j$ for some μ, α_is, and η_js. For example, consider **Table 2**. In this case, the relative effect of having at risk home status for low or medium adversity schools is a drop of 10 points in mean test score, however for highly adverse schools, the effect of an at risk home status is a drop of 15 points. Unlike cases where the additive model [7] holds, the effect of at risk home status depends on the level of school adversity, so there is no one number than can characterize the effect of at risk home status. It makes no sense to consider the effect of home conditions without specifying the school adversity. Similarly, the effects of school adversity change depending on home status. For example, going from low to high school adversity induces a 15 point drop for students whose homes are not at risk, but a 20 point drop for at risk students. Again, there is no one number than can characterize the change from low to high school adversity, so there is no point in considering this change without specifying the home risk status. One moral of this discussion is that when interaction exists, there is no point in looking at tests of main effects, because main effects are essentially meaningless. If there is no one number that describes the effect of changing from not at risk to at risk, what could $\alpha_1 - \alpha_2$ possibly mean?

In practice, analyses such as these are conducted on estimates of the μ_{ij}s, and the estimates are subject to variability.

A primary use of model [6] is to test whether this special group effects structure fits the data. Model [6] is used as a reduced model and is tested against the full model [5] that includes interaction. This test is referred to as a test of interaction. In particular, the interaction test is not a test of whether the $(\alpha\eta)_{ij}$s are all zero, it is a test of whether every possible definition of the $(\alpha\eta)_{ij}$s must be consistent with the two-way without interaction model. The easiest way to think about this correctly is to think about testing whether one can simply drop the $(\alpha\eta)_{ij}$s from model [5].

Table 2 Mean verbal test scores, interaction model

		j (School)		
	μ_{ij}	*1 (Low)*	*2 (Medium)*	*3 (High)*
i (Home)	1 (*N*)	110	105	95
	2 (*R*)	100	95	80

If the two-way without interaction model [6] fits the data, it is interesting to see if any special case (reduced model) also fits the data. Two obvious choices are fitting a model that drops the second factor (school) effects

$$y_{ijk} = \mu + \alpha_i + \varepsilon_{ijk} \qquad [8]$$

and a model that drops the first factor (home) effects

$$y_{ijk} = \mu + \eta_j + \varepsilon_{ijk} \qquad [9]$$

If model [8] fits the data, there is no evidence that the second factor helps explain the data over and above what the first factor explains. Similarly, if [9] fits the data, there is no evidence that the first factor helps explain the data over and above what the second factor explains.

Given model [8] with only the first factor effect, we can evaluate whether the data fit a reduced model without that effect,

$$y_{ijk} = \mu + \varepsilon_{ijk} \qquad [10]$$

This model comparison provides a test of whether the first factor is important in explaining the data when the second factor is ignored. Similarly we can start with model [9] and compare it to model [10]. If model [10] fits, neither factor helps explain the data.

Through fitting a series of models, we can test whether there is evidence for the interaction effects, test whether there is evidence for the second factor effects η_j when the first factor α_i effects are included in the model, test whether there is evidence for the second factor effects η_j when the first factor α_i effects are not included in the model, and perform two similar tests for the importance of the α_i effects. In the special case when the N_{ij}s are all the same, the test for α effects including ηs, that is, the test of model [6] versus model [9], and the test for α effects ignoring ηs, that is, the test of model [8] versus model [10], are identical. Similarly, the two tests for η effects are identical. While this identity greatly simplifies the analysis, it only occurs in special cases and is not generally applicable. Moreover, it does not extend to GLIMs such as log-linear models and logistic regression. The appropriate way to think about these issues is in terms of model comparisons.

Higher-Order ANOVA

The groups in a one-way ANOVA can also result from combining the levels of three or more factors. Consider a three-way cross-classification of Everitt's 97 students by further classifying them into students displaying or not displaying deviant classroom behavior. This determines $G = 12$ groups. The one-way ANOVA model $y_{gm} = \mu_g + \varepsilon_{gm}$, $g = 1, \ldots, G$, $m = 1, \ldots, N_g$ can be rewritten for three factors as $y_{ijkm} = \mu_{ijk} + \varepsilon_{ijkm}$ where the three factors are identified by $i = 1, \ldots, a$, $j = 1, \ldots, b$, $k = 1, \ldots, c$ so that $G = abc$, the group sample sizes are N_{ijk}, and $E(y_{ijkm}) = \mu_{ijk}$. In the example, we continue to use i and j to indicate home and school conditions, respectively, and now use $k = 1, 2$ to indicate classroom behavior with $k = 1$ being nondeviant.

In its most overparameterized form, a three-way ANOVA model is

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + (\eta\gamma)_{jk} + (\alpha\eta\gamma)_{ijk} + \varepsilon_{ijkm} \quad [11]$$

This includes a grand mean μ, main effects for each factor α_is, η_js, γ_ks, two-factor interactions $(\alpha\eta)_{ij}$s, $(\alpha\gamma)_{ik}$s, $(\eta\gamma)_{jk}$s, and a three-factor interaction $(\alpha\eta\gamma)_{ijk}$s. In model [11], dropping the redundant terms, that is, everything except the three-factor interaction terms, gives a one-way ANOVA model $y_{ijkm} = (\alpha\eta\gamma)_{ijk} + \varepsilon_{ijkm}$. The primary interest in model [11] is that it suggests a wealth of reduced models to consider.

The first order of business is to test whether the three factor interaction is necessary, i.e., test the full model [11] against the reduced model without the three-factor interaction

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + (\eta\gamma)_{jk} + \varepsilon_{ijkm} \quad [12]$$

Focusing on only the important parameters, model [12] is equivalent to $y_{ijkm} = (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + (\eta\gamma)_{jk} + \varepsilon_{ijkm}$. In fact, even this version of the model is overparameterized. Model [11] is equivalent to the one-way ANOVA model, so if the three-factor interaction test is significant, there is no simplifying structure to the treatments. Probably the best one can do is to think of the problem as a one-way ANOVA and draw whatever conclusions are possible from the groups.

If model [12] fits the data, we can seek simpler models or try to interpret model [12]. Conditioning on the levels of one factor, simplifies interpretations. For example, if $i = 1$, $y_{1jkm} = \mu + \alpha_1 + \eta_j + \gamma_k + (\alpha\eta)_{1j} + (\alpha\gamma)_{1k} + (\eta\gamma)_{jk} + \varepsilon_{1jkm}$ or $y_{1jkm} = [\mu + \alpha_1] + [\eta_j + (\alpha\eta)_{1j}] + [\gamma_k + (\alpha\gamma)_{1k}] + (\eta\gamma)_{jk} + \varepsilon_{1jkm}$. This is simply a two-factor model with interaction. If we change to $i = 2$, we again get a two-factor interaction model, one that has different main effects, but has the same interaction terms as when $i = 1$. For example, in Table 3 μ_{ijk}s satisfy model [12], that is, $\mu_{jkm} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + (\eta\gamma)_{jk}$ for some definitions of the parameters.

The key point in Table 3 is that, regardless of school adversity, the relative effect of not being at risk is always one point higher for nondeviants than for deviants. Thus, for high adversity the nondeviant home difference is 101–99 which is one point higher than the deviant home difference 99–98.

If model [12] is adequate, the next step is to identify which of the two factor interaction terms are important. For example, we can drop out the $(\eta\gamma)_{jk}$ term to get

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + \varepsilon_{ijkm} \quad [13]$$

Dropping unimportant parameters, this is equivalent to $y_{ijkm} = (\alpha\eta)_{ij} + (\alpha\gamma)_{ik} + \varepsilon_{ijkm}$. To interpret model [13], condition on the factor that exists in both interaction terms. In our example, this is home conditions. The resulting model for $i = 1$ is a no interaction model $y_{1jkm} = [\mu + \alpha_1] + [\eta_j + (\alpha\eta)_{1j}] + [\gamma_k + (\alpha\gamma)_{1k}] + \varepsilon_{1jkm}$ with a similar no interaction model for $i = 2$ but with different main effects. For example, suppose the m_{ij}s are given in Table 4. Rearranging Table 4 to group together categories with i fixed gives Table 5. For fixed home conditions, there is no interaction. For not at risk students, deviant behavior is associated with a one point drop and high school adversity is associated with a one point drop. For at risk students, deviant behavior is associated with a two point drop and, relative to low school adversity, medium and high adversities are associated with a one point and a three point drop, respectively.

Alternatively, we could eliminate both the $(\alpha\gamma)_{ik}$s and $(\eta\gamma)_{jk}$s from model (12) to get

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + (\alpha\eta)_{ij} + \varepsilon_{ijkm} \quad [14]$$

which is equivalent to $y_{ijkm} = \gamma_k + (\alpha\eta)_{ij} + \varepsilon_{ijkm}$. We can think of this as a model for no interaction in a two-factor analysis in which one factor is indicated by the pair ij and the other factor is indicated by k. In the example, this means there is a main effect for classroom behavior plus an effect for each of the six combinations of home and school conditions. In particular, consider Table 6. Here, deviant behavior is always associated with a one point drop but there is interaction between home and school. For low school adversity, there is no effect of home conditions but for medium or high adversity, being at risk is associated with a one point drop.

From model (14L50), we could then fit a model that involves only the main effects

$$y_{ijkm} = \mu + \alpha_i + \eta_j + \gamma_k + \varepsilon_{ijkm} \quad [15]$$

Model [15] is equivalent to $y_{ijkm} = \alpha_i + \eta_j + \gamma_k + \varepsilon_{ijkm}$. If model [15] is adequate, we could consider models that successively drop out the α_is, the η_js, and the γ_ks.

Fitting this sequence of successively smaller models, [11] then [12] then [13] then [14] then [15], then three models

Table 3 No three-factor interaction

		Adversity of school (j)					
		Low		*Medium*		*High*	
μ_{ijk}	*Home (i)*	*N*	*R*	*N*	*R*	*N*	*R*

	Deviant	100	100	100	99	100	99

with the main effects successively dropped out, provides one tool for analyzing the data. There are 36 different orders possible for sequentially dropping out the two-factor interactions and then the main effects. In the balanced case of $N_{ijk} = N$ for all i, j, k, the order of dropping the effects does not matter, so one can construct an ANOVA table to examine each of the individual sets of effects, that is, main effects, two-factor interactions, three-factor interaction. For unbalanced cases, one would need 36 different ANOVA tables, one for each sequence, so ANOVA tables are almost never examined except in balanced cases. (Two-factor models only generate two distinct ANOVA tables.) For unbalanced cases, instead of looking at the ANOVA tables, it is more convenient to simply report the *SSE* and *dfE* for all of the relevant models using a notation that identifies models by only their important parameters. For four or more factors, the number of potentially interesting models becomes too large to evaluate all of them.

After deciding on one or more appropriate models, the μ_{ijk}s can be estimated subject to the model and the models interpreted subject to the variability of the estimates.

To interpret a three-factor interaction, recall that just as a two-factor interaction exists when the effect of one factor changes depending on the level of the other factor, one can think of a three-factor interaction as a two-factor interaction that changes depending on the level of the third factor. However, it may be more productive to think of three-factor interaction in a three-factor model as simply specifying a one-way ANOVA. As with two-factor models, it makes little sense to test the main effects of a factor when that factor is involved in an important interaction. Similarly, it makes little sense to test that a lower-order interaction can be dropped from a model that includes a higher-order interaction involving all of the same factors.

A commonly used generalization of the ANOVA models is to allow some of the parameters to be unobservable random variables (random effects) rather than fixed unknown parameters. *see* Hierarchical Models: Random and Fixed Effects.

Generalized Linear Models

ANOVA is best suited for analyzing normally distributed data. These are measurement data for which the random observations are symmetrically distributed about their mean values. GLIMs use similar linear structures to analyze other kinds of data, such as count data and time to event data.

We can rethink two-way ANOVA models as independent observations y_{ijk} normally distributed with mean m_{ij} and variance σ^2, write $y_{ijkm} \sim N(m_{ij}, \sigma^2)$. The interaction model [5] has

$$m_{ij} = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij}$$

The no interaction model [6] has

$$m_{ij} = \mu + \alpha_i + \eta_j$$

Now consider data that are counts y_{ij} of some event. Assume the counts are independent Poisson random variables with means $E(y_{ij}) = m_{ij}$. The use of two subscripts indicates that the data are classified by two factors. For Poisson data the m_{ij}s must be nonnegative, so $\log(m_{ij})$ can be both positive and negative. Linear models naturally allow both positive and negative mean values, so it is natural to model the $\log(m_{ij})$s with linear models. For example, we might use the log-linear model

$$\log(m_{ij}) = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij}$$

or, without interaction,

$$\log(m_{ij}) = \mu + \alpha_i + \eta_j$$

These log-linear models are also appropriate for multinomial data and independent groups of multinomial data.

Similarly, if the data y_{ij} are independent binomials with N_{ij} trials and probability of success p_{ij}, then we can analyze the proportions $\widehat{p}_{ij} \equiv y_{ij}/N_{ij}$ with $E(\widehat{p}_{ij}) \equiv m_{ij}/P_{ij}$. Probabilities are defined to be between 0 and 1, the odds $p_{ij}/(1 - p_{ij})$ take positive values, and the log-odds can take any positive or negative value. It is natural to write linear models for the log-odds such as

$$\log[p_{ij}/(1 - p_{ij})] = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij}$$

or, without interaction,

$$\log[p_{ij}/(1 - p_{ij})] = \mu + \alpha_i + \eta_j$$

More generally, in GLIMs we create linear models for $g(m_{ij})$ using any strictly monotone function $g(\cdot)$, called a link function. The linear structures used for one-way ANOVA, two-way ANOVA, and higher-order ANOVA models all apply to GLIMs, and appropriate models can be found by comparing the fit of full and reduced models similar to methods for unbalanced ANOVA. In particular, cross-classified tables of counts often involve many factors.

We now examine in more depth ANOVA-type models for binomial data. Reconsider Everitt's 97 children cross-classified by the risk of their home environment and adversity of their school conditions. Rather than studying their verbal test score performance conditional on their classroom behavior as we did when discussing three-factor ANOVA we now examine models for whether the children display deviant or nondeviant behavior. In particular, we model the probability of a student falling into the deviant behavior category given their membership in the six home–school groups, write the probability of deviant behavior when in the ij group as p_{ij} and model the log-odds with ANOVA type models,

$$\log[p_{ij}/(1 - p_{ij})] = \mu_{ij}$$

The overparameterized model

$$\log[p_{ij}/(1-p_{ij})] = \mu + \alpha_i + \eta_j + (\alpha\eta)_{ij}$$

is equivalent to the original model. Neither of these models really accomplishes anything because they fit a separate parameter to every home–school category, so the models place no restrictions on the observations. The additive model

$$\log[p_{ij}/(1-p_{ij})] = \mu + \alpha_i + \eta_j$$

constitutes a real restriction on the parameters.

Suppose the log-odds, the μ_{ij}s, satisfy Table 7. These have the structure of an additive model. In this case the log-odds for deviant behavior are two larger for at risk homes than for not at risk homes, e.g., $2 = 0 - (-2) = 1 - (-1) = 3 - 1$. This means that the odds are $e^2 = 7.4$ times larger for at risk homes. In particular, the log-odds of deviant behavior for low adversity schools and not at risk homes is -2 so the odds are $O_{11} = e^{-2} = 0.135$ and the probability if $p_{11} = O_{11}/[1 + O_{11}] = 0.12$. Similarly, the odds and probability of deviant behavior for low adversity schools and at risk homes are $O_{21} = e^0 = 1$ and $p_{21} = 0.5$. The change in odds is $0.135 \times 7.4 = 1$. The 7.4 fold increase in odds is the same for all school conditions. Similarly, comparing low to high school adversities, the difference in log-odds is $3 = 1 - (-2) = 3 - 0$, so the odds of deviant behavior are $e^3 = 20$ times greater in highly adverse schools, regardless of the home situation. The odds of deviant behavior in highly adverse schools and not at risk homes is $O_{13} = e^1 = 2.7$ which is 20 times greater than $O_{11} = 0.135$, the odds for low adversity schools and not at risk homes.

An example of a nonadditive model has log-odds as shown in Table 8. For low adversity schools the log-odds only differ by 1, for medium adversity schools they differ by 2, and for high adversity schools they differ by 3. Thus the effect of home conditions on the log-odds depends on the level of school adversity.

Table 7 Log-odds: additive model

		j (School)		
	μ_{ij}	*1 (Low)*	*2 (Medium)*	*3 (High)*
i (Home)	1 (*N*)	−2	−1	1
	2 (*R*)	0	1	3

Table 8 Log-odds: nonadditive model

		j (School)		
	μ_{ij}	*1 (Low)*	*2 (Medium)*	*3 (High)*
i (Home)	1 (*N*)	−2	−1	1
	2 (*R*)	−1	1	4

Conclusions

The fundamental ANOVA model is the one-way model. It specifies different mean values for different groups. When the groups are identified as combinations of two or more factors, models incorporating main effects and interactions become a useful device for examining the underlying structure of the data. Appropriate models can be identified by fitting sequences of successively smaller models and using general testing procedures to identify the models within each sequence that fit well. Having identified a model, it is important to interpret what that model suggests about the underlying data structure. ANOVA models, the sequential model fitting procedures, and the interpretations apply to both balanced and unbalanced data and to GLIMs. The sequential model fitting simplifies in balanced ANOVA allowing for it to be summarized in an ANOVA table.

Abstract

This article draws together and briefly summarizes the most important questions raised by and discussed in the broad literature on analytical Marxism since its founding in the early 1980s.

Analytical Marxism is a cross-disciplinary school of thought that attempts to creatively combine a keen interest in some of the central themes of the Marxist tradition and the resolute use of analytical tools more commonly associated with 'bourgeois' social science and philosophy.

Marx is often interpreted as having used a 'dialectical' mode of thought that he took over, with modifications, from Hegel and that can be contrasted with conventional, 'analytical' thinking. Marx himself may have said and thought so. But according to analytical Marxists, one can make sense of his work, or at least of the main or best part of it, while complying with the strictest standards of analytical thought. This need not mean that all of what is usually called dialectics should be abruptly dismissed. For example, the study of the typically dialectical contradictions that drive historical change constitutes a challenging area for the subtle use of analytical thought (see Elster, 1978).

The resolute option for an analytical mode of thought does, however, imply that the research program stemming from Marx should by no means be conceived as the development of an alternative 'logic,' or of a fundamentally different way of thinking about capitalist development, or about social reality in general. It rather consists in practicing the most appropriate forms of standard analytical thought – using conventional conceptual analysis, formal logic and mathematics, econometric methods, and the other tools of statistical and historical research – to tackle the broad range of positive and normative issues broached in Marx's work. Analytical tools may have been developed and extensively used by 'bourgeois' social science and philosophy. This does not make them unfit, analytical Marxists believe, to rigorously rephrase and fruitfully develop some of the central tenets of the Marxian tradition.

Thus, the techniques characteristic of Anglo-American analytical philosophy can be used to clarify the meaning of key Marxian concepts as well as the epistemic status of the central propositions of the Marxian corpus and their logical relations with each other (see, e.g., Cohen, 1978). Formal models resting on the assumption of individually rational behavior, as instantiated by neoclassical economic theory and the theory of strategic games, can be used to understand the economic and political dynamics of capitalist societies (see, e.g., Przeworski, 1985; Carling, 1991). And the careful checking of theoretical conjectures against carefully collected and interpreted historical data can be used to test Marx's grand claims about transitions from one mode of production to another (see, e.g., Brenner et al. 1984). Making use of these tools does not amount to taking on board all the statements they have allegedly helped establish in the hands of conservative philosophers and social scientists. Nor is it meant to serve dogmatic defense of any particular claim Marx may have made. Rather, analytical Marxists view a competent, inventive, and critical use of these tools as an essential ingredient of any effective strategy both for refining and, if necessary, amending Marx's claims and for challenging the political status quo. There is, moreover, substantial disagreement among analytical Marxists as to what the proper methodological tools are (see, e.g., Bertram (2008) and Veneziani (2012) for a map of the differences between analytical Marxism proper and its 'rational choice' variant).

The areas in which analytical Marxists have been active range from medieval history to socialist economics and from philosophical anthropology to empirical class analysis. The issues about which they have been involved in the liveliest controversies include the following:

1. Are the central propositions of historical materialism to be construed as functional explanations, i.e., as explanations of institutions by references to the functions they perform? If so, are such explanations in the social realm as legitimate as in the biological? (See Cohen, 1978; Van Parijs, 1981; Elster, 1983.)
2. Is it possible, indeed is it necessary, for a Marxist to be committed to methodological individualism, i.e., to the view that all social scientific explanations should ultimately be phrased in terms of actions and thoughts by individual human beings? Or are there some admissible structuralist Marxian explanations that are irreducible to an individualistic perspective? (See Elster, 1982, 1985; Roemer, 1985; Wright et al., 1992.)
3. Is there any way of salvaging from the ferocious criticisms to which it has been subjected the so-called theory of the falling rate of profit, i.e., Marx's celebrated claim that capitalist economies are doomed to be crisis-ridden, owing to a systematic tendency for the rate of profit to fall as a result of the very process of profit-driven capital accumulation? If the criticisms are compelling, what are the consequences both for the methodology of Marxian economics and for Marxian crisis theory? (See Roemer, 1981; Elster, 1985; Van Parijs, 1993.)
4. Can one vindicate the labor theory of value, i.e., the claim that the labor time required to produce a commodity is the

ultimate determinant of its price, against the numerous objections raised against it? If not, does this have any serious consequence for positive Marxian theory, bearing in mind that Marx himself considered this theory essential to the explanation of capitalist profits? And does it have any serious consequence for Marxian normative theory (if any), bearing in mind that Marx's concept of exploitation is usually defined in terms of labor value? (See Steedman, 1977; Roemer, 1981; Cohen, 1989.)

5. Does Marx leave any room for ethical statements, i.e., statements about what a good or just or truly free society would be like, as distinct from statements about how a society could be more rationally organized or about what it will turn out to be by virtue of some inexorable laws of history? Or should one instead ascribe to him a consistently amoralist position and, if the latter, can such a position be defended? (See Wood, 1981; Elster, 1985; Geras, 1985; Cohen, 1989.)
6. Can the concept of exploitation – commonly defined as the extraction of surplus labor, or as the unequal exchange of labor value – be made independent of the labor theory of value? Can it be extended to deal with late-capitalist or postcapitalist societies, in which the possession of a scarce skill, or the incumbency of some valued job, or the control over some organizational asset may be at least as consequential as the ownership of material means of production? Can such a more or less generalized concept of exploitation provide the basis for an empirically fruitful concept of social class? By providing a precise characterization of what counts as an injustice, can it supply the core of an ethically sensible conception of justice? (See esp. Roemer, 1982; Wright, 1985; Wright et al., 1989; Wright, 1995)
7. How can the Marxian commitment to equality (if any) be rigorously and defensibly formulated? Could the egalitarian imperative that motivates the demand for the socialization of the means of production also be satisfied by an equal distribution of the latter, or by a neutralization of the impact of their unequal distribution on the distribution of welfare? To what extent is this imperative compatible with every individual owning (in some sense) herself, as taken for granted, it would seem, in the typically Marxian idea that workers are entitled to the full fruits of their labor? (See Roemer, 1994a,b; Cohen, 1995.)
8. After the collapse of East European socialism, is it possible to reshape the socialist project in a way that takes full account of the many theoretical and practical objections that have been raised against it? Can a system be designed in which the social ownership of the means of production is combined with the sort of allocative and dynamic efficiency commonly ascribed to capitalist labor and capital markets? (See Roemer, 1994a.) Or should the radical alternative to capitalism as we know it rather be found in a "capitalist transition toward communism" through the introduction and gradual increase of an unconditional basic income or in a highly egalitarian redistribution of privately owned assets? (See van der Veen et al., 1986; Bowles et al., 1998.)

The boundaries of analytical Marxism are unavoidably fuzzy. Defined by the combination of a firm interest in some of the central themes of the Marxist tradition and the uninhibited use of rigorous analytical tools, it extends far beyond, but is strongly associated with, the so-called September Group founded in 1979 by the Canadian philosopher G.A. Cohen (Oxford) and the Norwegian social scientist Jon Elster (Columbia). The group has crystallized an attitude into a movement, by endowing it with a name, a focus, and a target for criticism (see Roemer, 1985 and 1993; Nielsen and Ware, 1989; Mayer, 1994). Having started with a critical inventory of Marx's heritage, it gradually took a more prospective turn, with a growing emphasis on the explicit elaboration and thorough defense of a radically egalitarian conception of social justice (see Cohen, 1995, 1999; Van Parijs, 1995; Roemer, 1996) and a detailed multidisciplinary discussion of specific reforms (see Van Parijs, 1992; Roemer, 1998; and the volumes in the "Real Utopias Project" directed by Erik O. Wright). This development has arguably brought analytical Marxism considerably closer to left liberal social thought than to the bulk of explicitly Marxist thought. Much contemporary work on analytical Marxism asks whether there are any distinctive Marxist (as opposed to egalitarian liberal) commitments in the realm of social and political theories and, if so, what these are (e.g., Levine, 2003; Veneziani, 2012).

Abstract

The core idea of analytical sociology is the importance of mechanism-based understanding of social processes. Sociological theories should provide clear and precise accounts of the social mechanisms by which the intentional activities of social agents bring about social phenomena. Theories about social mechanisms can be characterized as theories of middle range as they provide clear, precise, and simple explanations for specified aspects of range of different phenomena, without pretense of being able to explain all social phenomena. Intentional action plays an important role in social mechanisms, but the analytical sociology perspective suggests that our account of human agency should be based on findings and theories of psychological and cognitive sciences rather than on some preconceived ideas about human motivation or cognitive processing. Much of the development of mechanism-based knowledge consists of developing how-possibly explanation schemes. Agent-based computer simulations can be very useful for this kind of endeavor.

Analytical sociology is a reform movement within sociology and social theory. Its identity is not based on a common object of study, a shared historical tradition in sociological theory, or an empirical research method. Rather, it is founded on the idea that the social sciences should do more than describe and classify social processes. According to its supporters, the primary epistemic aim of the social sciences should be causal explanation of social phenomena. Sociological theory should aim to develop clear and precise accounts of the social mechanisms by which the intentional activities of social agents bring about social phenomena (Hedström, 2005; Manzo, 2010).

The emphasis on causal explanation sets analytical sociology apart from the interpretive – cultural studies-influenced – sociology that either shuns any explanatory ambitions or regards social scientific explanations as noncausal and noncontinuous with the natural sciences. For analytical sociology, the same causal and explanatory ideals that motivate natural sciences should also drive the social sciences. The natural sciences are a source of occasional inspiration and evidential support, rather than an enemy. The emphasis on mechanism-based explanation separates analytical sociology from the quantitatively oriented and variable-based sociology that prefers to stay very close to empirical data and provides explanations mostly on an ad hoc basis. Analytical sociologists do not oppose the use of quantitative data but they argue that social research should be more theory driven and that causal claims should be supported by a theoretical understanding of the causal mechanisms underlying the observed statistical regularities. Finally, the emphasis on precision and clarity and on the importance of tightly linking theory and empirical research contrasts analytical sociology with mainstream social theory. It advocates the idea that sociologists should focus on theories of middle range that can be tested and elaborated via empirical research.

The historical roots of analytical sociology can be traced back to the works of late nineteenth and early twentieth century sociologists such as Max Weber and Alexis de Tocqueville, and to prominent mid-twentieth century sociologists such as the early Talcott Parsons and Robert K. Merton. Among contemporary social scientists, Jon Elster, Raymond Boudon, Thomas Schelling, and James Coleman have profoundly influenced the analytical approach. Although they are rather different types of scholars, they complement each other in important ways, and they all share a commitment to precise, abstract, and action-based explanations.

The current generation of analytical sociologists is building upon the foundations laid by these authors aiming to develop an analytical middle-range approach to sociological theory that avoids the somewhat empiricist and eclectic tendencies of Merton's original middle-range approach. Examples of the recent work in this tradition can be found in anthologies edited by Hedström and Swedberg (1998), Hedström and Bearman (2009), Demeulenaere (2011), and in a monograph by Hedström (2005).

Analytical Realism

The philosophy underlying analytical sociology could be characterized as realistic in a number of respects. First, in contrast to empiricist and instrumentalist views, it regards explanation as the principal epistemic aim of science. Sociological theories are not merely intellectual constructions that can be used for the purposes of prediction and control of social events. The primary goal is to represent causal processes that generate the observable phenomena. For the same reason, sociological theories that merely aim to classify social processes and institutions are regarded as misdirected and lacking proper ambition. The accurate description of social phenomena is a very important part of the social sciences, but it should not be the only one.

Second, in contrast to empiricist and behaviorist views, it does not regard the use of theoretical concepts to be illegitimate or suspicious. As in the natural sciences, social scientists can employ theories that refer to unobservable entities and processes. There is no need to reduce them to observable variables. According to analytical sociologists, it is not possible to represent general causal knowledge in the social sciences as

 http://dx.doi.org/10.1016/B978-0-08-097086-8.44071-7

invariant empirical regularities. Rather, the social scientific knowledge is based on understanding the causal mechanisms underlying observable regularities. In the same spirit, analytical sociologists employ the conceptual scheme of intentional psychology that refers to unobservable psychological states like beliefs and desires. Furthermore, intentional explanations are regarded as causal explanations.

Third, contrary to the instrumentalist attitude common among many rational choice theorists, especially economists, analytical sociologists regard explanation as factive. It is not enough that the theory or model 'saves the phenomena'; it should represent the essential features of the actual causal structure that produces the observed phenomena. Thus, analytical sociology does not accept the 'as if' attitude displayed by many economists; those theoretical assumptions that have a central explanatory role should be both empirically valid and compatible with the results of other scientific fields.

Fourth, analytical sociology embodies the realistic spirit by not letting the considerations of elegance, simplicity, or tractability to override the aim of accurately describing the real causal mechanisms producing the observable phenomena. Contrary to a widespread practice among mathematically oriented economists and rational choice sociologists, analytical sociologists do not accept the instrumentalist attitude according to which assumptions are instruments that can be freely tinkered with until one arrives at simple and elegant models. Parsimonious models with clear analytical solutions deserve praise only if they are not achieved at the cost of implausible theoretical assumptions.

Rather than seeking excessively precise fictions, social scientists should aim for theoretical assumptions known to be at least roughly correct about the phenomenon that they are analyzing. Such a modest and realist strategy characterizes some of the best theoretical work in sociology. Robert K. Merton's work on self-fulfilling prophecies (Merton, 1968) provides a good example. At the core of this elegant and highly influential piece of work is the assumption that the actions of others influence individuals' beliefs and subsequent actions. However, Merton never specified any precise model of the decision calculus for the individuals. Although such model would be possible, it would not add any insights to those found in Merton's analysis. Formalization often is required for explaining social phenomena but, if the model does not properly describe action principles observed in the real world, it is of little explanatory use. It is more advisable to base the analysis on clear and empirically plausible assumptions about the actions and interactions of individuals, as Merton did, and then on this basis develop theoretical models that allow us to get a handle on the social outcomes that the actors are likely to bring about. Such analyses either generate tendency statements about patterns likely to be observed or suggest plausible processes through which the phenomena to be explained could have been brought about. More precision might be desirable, but not excessive precision that simply amounts to precisely stating and assuming to be true what is known to be untrue.

Like most economists, but unlike some sociologists, analytical sociologists regard the method of isolation and abstraction as an indispensable part of theory development: empirical reality is complex and it is futile to try to capture it as a whole. Building a complex model of a complex phenomenon does not provide much explanatory insight. For this reason, the strategy of intentional simplification is preferable: the scientist tries to capture the central features of the phenomenon first. The achievement of understanding is only possible by studying quite simplified but realistic theoretical models and gradually increasing the complexity of these models. The employment of this research strategy does not commit the scientist to the denial of the complexity of social life. To the contrary, the strategy of model building intends to avoid the hubris associated with one sweep attempt to capture complexity. According to analytical sociology, an adequate sociological theory is abstract, realistic, and precise, and it seeks to explain specific social phenomena on the basis of explicitly formulated theories of action and interaction.

Social Mechanisms

The core idea of analytical sociology is that sociological theory explains by specifying causal mechanisms that bring about social phenomena. The specifically social causal mechanisms are called social mechanisms (Hedström and Ylikoski, 2010).

Analytical sociologists are dissatisfied with the traditional covering-law account of explanation that has a large number of philosophical problems and embarrassing counterexamples. It has also provided justification for the use of 'black box' explanations in the social sciences as it does not require that the mechanism linking explanans and explanandum be specified in order for an acceptable explanation to be at hand. This omission has given leeway for sloppy scholarship. In contrast to this fundamentally empiricist account of explanation, analytical sociologists require that explanations should articulate causal mechanisms rather than simply subsume phenomena under empirical generalizations (Hedström and Ylikoski, 2010).

Analytical sociology draws from recent debates about the importance of mechanism-based explanation in the social sciences and philosophy of science (Darden, 2006; Craver, 2007; Hedström and Ylikoski, 2010). Because the entities and processes studied by different sciences are quite heterogeneous, it is difficult to propose a mechanism definition that would both be informative and cover all examples of mechanisms. Some disciplines, such as cell biology (Bechtel, 2006) and the neurosciences (Craver, 2007), study highly integrated systems, whereas others, such as evolutionary biology and the social sciences, study more dispersed phenomena. For this reason, a characterization of a mechanism that applies to one field might not be informative when applied to another.

However, some general ideas are shared by most accepted mechanism definitions (Hedström and Ylikoski, 2010). First, a mechanism is identified by the kind of effect or phenomenon it produces. A mechanism is always a mechanism for something (Darden, 2006). Second, a mechanism is an irreducibly causal notion. It refers to the entities of a causal process that produces the effect of interest. Third, the mechanism has a structure. When a mechanism-based explanation opens the black box, it discloses this structure. It turns the black box into a transparent box and makes visible how the participating entities and their properties, activities, and relations produce the effect of interest. Fourth,

mechanisms form a hierarchy. While a mechanism at one level presupposes or takes for granted the existence of certain entities with characteristic properties and activities, it is expected that there are lower level mechanisms that explain them (Craver, 2007). It is an inherent feature of the mechanism view that the entities and mechanisms of various sciences are ultimately related to each other. Although the explanatory entities and mechanisms employed by one science always bottom out somewhere (Darden, 2006) and are therefore taken as fundamental, their fundamental status is relative because they are mechanistically explainable by other fields of science.

A mechanism-based explanation describes the causal process selectively. It does not aim at an exhaustive account of all details but seeks to capture the crucial elements of the process by abstracting away the irrelevant details. The relevance of entities, their properties, and their interactions is determined by their ability to make a relevant difference to the outcome of interest. If the presence of an entity or of changes in its properties or activities truly does not make any difference to the effect to be explained, it can be ignored. This counterfactual criterion of relevance implies that mechanism-based explanations involve counterfactual reasoning about possible changes and their consequences (Ylikoski, 2011).

Roughly, mechanism-based explanations have two kinds of explananda. First, they might address particular empirical facts. In such cases, the description of the mechanism is often a modified adaptation and combination of more general mechanism schemes. Second, they might address stylized facts. Although the explanation of particular empirical facts is the ultimate goal of mechanism-based theory development, most of the time theorists are addressing highly stylized theoretical explananda that do not necessarily have close resemblance to any particular empirical fact. Consider, for example, the small-world problem of Milgram (1967). Watts and Strogatz (1998) identified some salient and abstract features of the small-world problem – average path length and local clustering – and developed a model that could explain them. The explanation of simplified and heavily idealized facts such as those identified by Watts and Strogatz results in mechanism schemes with wide application domains. By establishing how stylized facts can in principle be explained, theorists contribute to the toolbox of semigeneral mechanisms.

Apart from providing explanatory understanding as to why the dependency holds, the information about the causal mechanisms also provides justification for causal claims. Distinguishing between real causal claims and spurious statistical associations is a major challenge in the social sciences. The real causal dependences are transmitted via causal processes and the search for causal mechanisms directs the attention to these processes.

The idea of causal mechanisms is related to broader ideas about the growth and organization of scientific knowledge. In mechanism-based accounts, scientific knowledge is embedded in mechanism schemes and not in empirical generalizations as in more traditional empiricist accounts. According to this view, scientific knowledge expands by adding items to or improving upon items already present in the toolbox of possible causal mechanisms. Understanding accumulates as the knowledge of mechanisms gets more detailed and the number of known mechanisms increases. This vision of knowledge does not require that mechanisms be ultimately organized into a grand unified theory. It is only required that the accounts of mechanisms provided by different disciplines be mutually compatible and that they form an integrated web in which mechanisms at lower levels of organization explain the mechanisms that higher level disciplines take for granted. For example, psychology explains (and corrects) the assumptions that social scientists make about human cognitive processes.

The mechanism idea is important in a highly specialized and fragmented discipline like sociology. Although empirical data, research methods, and substantial theories differ from one subfield of sociology to another, the general ideas about possible causal mechanisms are something these fields could share and thereby benefit from each other's work. In this vision, sociological theory provides a set of explanatory tools that can be employed and adapted to particular situations and explanatory tasks. The mechanisms are (semi) general in the sense that most of them are not limited to any particular application. For example, the same type of mechanism can be used for (partially) explaining residential segregation (Bruch and Mare, 2006) and success in cultural markets (Salganik and Watts, 2009).

Theories of Middle Range

This mechanism-based vision of knowledge has much in common with Robert K. Merton's idea of sociological theories of the middle range (Merton, 1968). A theory of middle range is a clear, precise, and simple type of theory that can be used for partially explaining a range of different phenomena, but that makes no pretense of being able to explain all social phenomena, and that is not founded upon any form of extreme reductionism in terms of its explanans. Middle-range theories isolate a few explanatory factors that explain important but delimited aspects of the outcomes to be explained (Hedström and Udéhn, 2009).

Merton's account of self-fulfilling prophesies provides a clear example of a social mechanism. The basic idea behind the theory of the self-fulfilling prophecy is what Merton referred to as the Thomas theorem: "If men define situations as real, they are real in their consequences" (Merton, 1968: p. 475). Merton focused on the process through which an initially false belief evokes behavior that eventually makes the false belief come true. His example was a run on a bank. Once a rumor of insolvency gets started, some depositors are likely to withdraw their savings, acting on the principle that it is better to be safe than sorry. These withdrawals strengthen others' beliefs that the bank is in financial difficulties, partly because the withdrawals may actually hurt the financial standing of the bank, but more importantly because the act of withdrawal in itself signals to others that something might be wrong with the bank. This causes even more withdrawals, which further strengthens the belief, and so on. By this mechanism, even an initially sound bank may go bankrupt if enough depositors withdraw their money in the (initially) false belief that the bank is insolvent. The theory of the self-fulfilling prophecy is a good example of a social mechanism as (1) it refers to a dynamic process; (2) the collective outcome is unintended by the individuals who

bring it about; (3) the process is driven by social interactions between individuals; and (4) the process is endogenous and self-reinforcing. The mechanism is in principle quite general and it can be used to explain a range of different types of phenomena (Biggs, 2009).

Social Explananda and Individual Action

The main focus of analytical sociology is on social (as distinct from psychological) explananda that are not definable by reference to any single member of the collectivity. Important examples of such properties include (Hedström, 2005)

- typical actions, beliefs, or desires among the members of a collectivity;
- distributions and aggregate patterns such as spatial distributions and inequalities;
- topologies of networks that describe relationships between members of a collectivity; and
- informal rules or social norms that constrain the actions of the members of a collectivity.

A key insight of analytical sociology is that explanations that directly relate macrovariables to each other are unsatisfactory. They do not specify the causal mechanisms by which the changes in one macrovariable brings about changes in another. Deeper explanatory understanding requires opening up the black box and finding the causal mechanisms that have generated the macrolevel pattern. Rather than analyzing relationships between phenomena exclusively on the macrolevel, one should identify the situational mechanisms by which social structures constrain individuals' action and cultural environments shape their desires and beliefs, describe the action formation mechanisms according to which individuals choose how to act, and specify the transformational mechanisms by which individuals, through their actions and interactions, generate various intended and unintended social outcomes. Only by understanding the whole chain of situational, action-formation, and transformational mechanisms, have we made sense of the observed macrolevel relationship (Coleman, 1990; Hedström and Swedberg, 1998).

This emphasis on detailing mechanisms implies that explanations should refer to individuals, their relationships, and their actions (in addition to whatever other social properties are relevant for explaining the causes and consequences of their actions). It is important to recognize that the basic building blocks of social explanations are not mutually independent actions performed by atomistic individuals, however. Rather, individuals' actions typically are oriented toward others, and their relations to others therefore are central when it comes to explaining why they do and what they do. In addition, social relations are central for explaining why, acting as they do, individuals bring about the social outcomes they do. Consider, as an example, the case of vacancy chains as analyzed by White (1970). A retirement, motivated perhaps by a desire for a more leisurely life, creates an opportunity for others, that is, a job vacancy waiting to be filled by a new occupant. The vacancy generated by the retirement is filled by another individual whose reason for taking the job, perhaps, is to attain more status, a higher salary, or just a change in venue, but this creates another vacancy in this person's old job, and in this way vacancy chains create social interdependencies that are important for explaining mobility. Individuals' desires – for retirement, promotion, status, or change in venue – motivate the system. Without such orientations, people may not move. But explanatory understanding is only achieved by recognizing that actions take place in relational structures that in this case channel mobility opportunities and thereby explain why we observe what we observe (Hedström and Bearman, 2009b).

This line of reasoning does not imply commitment to the doctrine of methodological individualism (Ylikoski, 2012). Most formulations of methodological individualism are much stronger than the mechanism-based perspective requires (Udéhn, 2001). Some form of structural individualism (Coleman, 1990; Hedström, 2005) is sufficient for the purposes of mechanism-based explanations of social phenomena. Structural individualism is a doctrine according to which all social facts, their structure and change, are in principle explicable in terms of individuals, their properties, actions, and relations to one another. Structural individualism differs from most formulations of methodological individualism by emphasizing the explanatory importance of relations and relational structures. It does not require that all explanatory facts are facts about individual agents in the strict sense: facts about topologies of social networks; about distributions of beliefs, resources, or opportunities; and about institutional or informal rules and norms can have a significant role in mechanism-based explanations.

Intentional action plays an important role in social mechanisms, but the idea of a social mechanism in itself does not tell us how to conceptualize human action. Rather than relying on some preconceived ideas about human motivation or cognitive processing, analytical sociology perspective suggests that our account of human agency should be based on findings and theories of psychological and cognitive sciences. Analytical sociology's focus on social, rather than psychological, mechanisms has some methodological implications, however. Understanding of complex phenomena is only possible in a piecemeal way, so sociologists must abstract away from many details of human mental life. Only those aspects of cognition that are relevant for the explanatory task at hand should be included in the explanation, and the explanatory task thus determines how rich the psychological assumptions must be.

So although the mechanism-based approach emphasizes the importance of action in the explanation of social phenomena, it does not subscribe to an axiomatic vision according to which a specific action theory should be used for all purposes. As different theories of action emphasize different aspects of human action, the choice between them should be made on methodological grounds. In some modeling contexts, rational choice theory is a natural choice, while in contexts where the emphasis is on the habitual dimensions of human actions, analytical sociologist might choose to employ some psychological dual-process theory (Wilson, 2002). However, for many social scientific purposes, a relatively simple desire–belief–opportunity model will be sufficient (Hedström, 2005). This simple theory provides a building block for accounts of social mechanisms of interaction through which

the actions of some actors may come to influence the beliefs, desires, opportunities, and actions of others.

Historically, analytical sociology has some of its roots in the tradition of rational choice sociology. However, current analytical sociology does not have any special commitment to the assumptions of rational choice theory. There is nothing in the idea of a mechanism-based explanation that would require the explanation to be articulated in terms of rational choice theory. On the contrary, the requirement that mechanism-based explanations cite actual causes of the phenomenon to be explained often makes rational choice explanations unacceptable, as they are built on implausible psychological and sociological assumptions. Empirically false assumptions about human motivation, cognitive processes, access to information, or social relations cannot bear the explanatory burden in a mechanism-based explanation. In order for unrealistic psychological and social assumptions to be acceptable, they must be simplifying idealizations that help the modeling but do not affect the central explanatory relationships in any crucial manner. This rarely is the case in rational choice theory. For this reason, it is a mistake to take analytical sociology as rebranded rational choice sociology. Rather than relying on some preconceived ideas about human motivation or cognitive processing, the mechanism-based perspective suggests that our account of human agency should be based on findings and theories of psychological and cognitive sciences.

Agent-Based Modeling

A recent development in analytical sociology has been the use of agent-based computer simulations (Hedström, 2005; Macy and Flache, 2009; Squazzoni, 2012). Much of the development of mechanism-based knowledge consists of developing how-possibly explanation schemes. These schemes are not intended to explain any particular empirical facts directly, but to provide a general understanding of how things could work. Given the limitations of experimental methods and the complexity of social phenomena, computer simulations are important for this kind of endeavor. Computer simulations allow systematic exploration of consequences of modeling assumptions and make it possible to model much more complex phenomena than was possible earlier.

The promise of agent-based simulation is based on the fact that the dynamics observed at the social level typically are complex and hard to understand, but often it is possible to describe the basic cogs and wheels of these social processes with rather simple models. Macrolevel outcomes and relationships tell us very little about why we observe the macrolevel outcomes and the relationships we observe. Only by explicitly considering the microlevel actions and relations and how they unfold over time can macrolevel outcomes be explained. This basic insight is at the heart of analytical sociology: to understand collective dynamics, we must study the collectivity as a whole, but we must not study it as a collective entity.

One important feature of agent-based simulations is that they do not impose any a priori constraints on the mechanisms assumed to be operating. Unlike rational choice theory, agent-based modeling is not based on any specific theory of action or interaction. It is a methodology for deriving the social outcomes that groups of interacting actors are likely to generate, whatever the action logics or interaction structures may be. Agent-based simulations should not only be regarded as a tool for theoretical exploration, however. Empirically calibrated agent-based models make it possible to integrate theoretical ideas with the results of empirical research (e.g., Bruch and Mare, 2006).

Conclusion

Mechanism talk is becoming increasingly popular in the social sciences. Many sociologists use the word 'mechanism' in a loose sense without any commitment to the type of mechanism-based explanatory strategy focused upon here. Underlying the mechanism-based approach is a commitment to realism: the explanations should reflect the causal processes responsible for the phenomenon to be explained. This requires stringency in theoretical practice and imagination in the design of empirical research.

One of the basic premises of analytical sociology is that proper understanding of collective processes requires that the researchers pay attention to the entities that mechanisms are made of (the agents, their properties, actions, and relations) rather than treating them as opaque entities. This dogma of analytical sociology means that theoretical models as well as empirical research must focus on actions and relations and how they unfold over time. This basic principle has far-reaching consequences for the type of empirical data that needs to be used as well as for the type of theoretical work that is needed. As far as data and empirical research are concerned, longitudinal data with relational information are essential, given that the basic entities of social mechanisms are actors, their actions, and relations. Similarly, the mechanism approach has considerable consequences for how theoretical work ought to be conducted: rigorous theorizing is needed that explicitly considers the microlevel mechanisms at work and the dynamic processes that they give rise to.

Anaphora

Yan Huang, University of Auckland, Auckland, New Zealand

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Anaphora is definable as a relation between two or more linguistic elements, in which the interpretation of one (called an anaphoric expression) is in some way determined by the interpretation of the other (called an antecedent). This essay defines anaphora and presents typologies of anaphora on the basis of syntactic categories, truth-conditions, and reference-tracking systems. It also provides an authoritative, up-to-date, and critical survey of the latest theoretical treatments of intrasentential anaphora, comparing and contrasting the two main rival approaches: grammatical and pragmatic.

Defining Anaphora

The term 'anaphora' comes from the Greek word *αναφορά*, which means 'carrying back.' In contemporary theoretical linguistics, there are three distinct senses of 'anaphora/anaphor/anaphoric.' ((1) A relation between two or more linguistic elements, in which the interpretation of one (called an anaphoric expression) is in some way determined by the interpretation of the other (called an antecedent). In other words, in an anaphoric relation, an anaphoric expression takes its meaning or reference from its antecedent. Many aspects of anaphora are pragmatic in nature. (2) An anaphoric relationship in which the antecedent comes earlier than the anaphoric expression. Originally, 'anaphora' was a term for a relation 'up' (Greek *aná*). Anaphora (2) is also called variously forward anaphora, backward-looking anaphora, or retrospective anaphora.) In the first place, the term can be used to refer to a relation between two or more linguistic elements, in which the interpretation of one (called an anaphor or anaphoric expression) is in some way determined by the interpretation of the other (called an antecedent). Linguistic elements that can be employed to encode an anaphoric relation in this general sense range from gaps (or empty categories) through reflexives to various discourse reference-tracking systems like switch function (see the section 'Anaphora and Discourse: Reference-Tracking Systems'). (Keeping track of the various entities referred to in an ongoing discourse. Linguistic mechanisms that are deployed for such a purpose are called reference-tracking systems. Cross-linguistically, four main types of reference-tracking systems can be identified:(i) gender or class systems, (ii) switch-reference systems, (iii) switch-function systems, and (iv) inference systems.) Secondly, the term can be deployed in Chomsky's (1981, 1995) generative grammar to refer to a noun phrase (NP) with the features [+anaphoric, −pronominal] 'anaphor' versus an NP with the features [−anaphoric, +pronominal] 'pronominal.' Thus, the reflexive in (1) is treated as an anaphor, and the pronoun in (2) as a pronominal in the Chomskian tradition.

1. Obama praised *himself*.
2. Obama praised *him*.

Thirdly, the term can be used for reference to an anaphoric expression whose antecedent comes earlier, as in (3), as opposed to the term 'cataphora/cataphor/cataphoric,' where the antecedent comes later, as in (4). (An anaphoric (1) relationship in which the antecedent of an anaphoric expression comes later than the anaphoric expression itself. Put the other way round, an expression 'looks forward' for its antecedent. Cataphora is a term for a relation 'down' (Greek *katá*). Also called variously anticipatory anaphora, backward anaphora, forward-looking anaphora, and retrospective anaphora.)

3. After the zoo keeper was wounded, *he* was taken to a hospital.
4. After *he* was wounded, the zoo keeper was taken to a hospital.

Both anaphora and cataphora in this sense can be subsumed under the term 'endophora/endophor/endophoric' (a term that is sometimes used to subsume anaphora and cataphora, viewed as a relation in which an anaphoric expression and its antecedent are within ('*endo-*') the same sentence or discourse), referring to the relation where the anaphoric/cataphoric expression and its antecedent are within the same conversation or text. In contrast, by the term 'exophora/exophor/exphoric' (in opposition to endophora/endophoric, the term refers to a relation in which the referent of an anaphoric expression lies outside ('*exo-*') what is said or written. Also called contextual anaphora and situational anaphora) is meant that the antecedent of an anaphoric, or more accurately a deictic, or indexical, expression lies outside the conversation or text. This is exemplified in (5).

5. (Referents in the physical environment, and with selecting gesture)
   She's not the principal. *She* is.

Anaphora can be intrasentential, in which case the anaphoric expression and its antecedent occur within a single simplex or complex sentence. It can also be discoursal, in which case the anaphoric expression and its antecedent cross sentence boundaries. In addition, there are anaphoric devices that lie in between pure intrasentential anaphora and pure discourse or text anaphora.

Anaphora is at the center of twenty-first-century research on the interface between syntax, semantics, and pragmatics in theoretical linguistics. It is also a subject of key interest in psycho- and computational linguistics, and to work on the philosophy of language, and language in cognitive science. It has aroused this interest for a number of reasons. To begin with, anaphora represents one of the most complex phenomena of natural language, which, in itself, is the source of fascinating problems. Secondly, anaphora has long been regarded as one of the few 'extremely good probes' in furthering our understanding of the nature of the human mind, and thus in facilitating an answer to what Chomsky considers to be the fundamental problem of linguistics, namely, the logical problem of language acquisition – a special case of Plato–Russell's problem. In particular, certain aspects of anaphora have repeatedly been claimed by Chomsky to furnish evidence for the argument that human beings are born equipped with some internal, unconscious knowledge of language, known as the language faculty. Thirdly, anaphora has been shown to interact with syntactic, semantic, and pragmatic factors. Consequently, it has provided a test bed for competing hypotheses concerning the relationship between syntax, semantics, and pragmatics in linguistic theory.

Typologies of Anaphora

Anaphora can be classified on the basis of (a) syntactic categories, (b) truth-conditions, and (c) discourse reference-tracking systems.

Anaphora and Syntactic Categories

In terms of syntactic category, anaphora falls into two main groups: (a) NP- (noun phrase-), including N- (noun-), anaphora, and (b) VP- (verb phrase-) anaphora. In an NP-anaphoric relation, both the anaphoric expression and its antecedent are in general NPs, and both are potentially referring expressions (6). NP-anaphora corresponds roughly to the semantically defined type of 'identity of reference' anaphora. It can be encoded by gaps (or empty categories), pronouns, reflexives, epithets, proper names, and definite descriptions. By contrast, in an N-anaphoric relation, both the anaphoric expression and its antecedent are a noun, rather than an NP, and neither is a potentially referring expression (7). N-anaphora corresponds roughly to the semantically defined type of 'identity of sense' anaphora. Linguistic elements that can be used as an N-anaphor include gaps, pronouns, and nouns.

6. Bill thought that *he* had reached a different conclusion.
7. John's favorite composer is Bach, but Mary's Ø is Handel.

The other main category is VP-anaphora. Under this rubric, five types may be isolated: (a) VP-ellipsis, in which the VP of the second and subsequent clauses is reduced (8); (b) gapping, in which some element (typically a repeated, finite verb) of the second and subsequent conjuncts of a coordinate construction is dropped (9); (c) sluicing, which involves an elliptical construction consisting only of a *wh*-phrase (10); (d) stripping, an elliptical construction in which the ellipsis clause usually contains only one constituent (11); and (e) null complement anaphora, an elliptical construction in which a VP complement of a verb is omitted (12).

8. John adores Goya's paintings, and Steve does, too.
9. Reading maketh a full man; conference a ready man; and writing an exact man.
10. John donated something to Médecins Sans Frontières, but I don't know what.
11. Pavarotti will sing 'Nessun dorma' again, but not in Hyde Park.
12. Mary wanted to swim the English channel, but his father didn't approve.

Anaphora and Truth-Conditions

From a truth-conditional, semantic point of view, anaphora can be divided into five types: (a) referential anaphora, one that refers to some entity in the external world either directly or via its co-reference with its antecedent in the same sentence or discourse (13); (b) bound-variable anaphora, which is interpretable by virtue of its dependency on some quantificational expression in the same sentence or discourse, thus seeming to be the natural language counterpart of a bound variable in first-order logic (14); (c) E- (Evans-) type anaphora, one which, for technical reasons, is neither a pure referential anaphor nor a pure bound-variable anaphor, but which nevertheless constitutes a unified semantic type of its own (15); (d) anaphora or pronoun of 'laziness,' so called because it is neither a referential anaphor nor a bound-variable anaphor, but functions as a shorthand for a repetition of its antecedent (16); and (e) bridging cross-reference anaphora, one that is used to establish a link of association with some preceding expression in the same sentence or discourse via the addition of background assumption (17).

13. The farmer said that he has aerated the soil this morning.
14. Every little girl wishes that she could visit the land of Lilliput.
15. Most people who bought a donkey have treated it well.
16. The man who gave his paycheck to his wife was wiser than the man who gave it to his mistress.
17. John dined in an Italian restaurant. The waiter was very handsome.

Anaphora and Discourse: Reference-Tracking Systems

Reference-tracking systems are mechanisms employed in individual languages to keep track of the various entities referred to in an ongoing discourse. In general, there are four major types of reference-tracking systems in the world's languages: (a) the gender/class system, (b) the switch-reference system, (c) the switch-function system, and (d) the inference system.

In a gender or class system, an NP or (less frequently) a VP is morphologically classified for gender or class according to its inherent features, and is tracked through a discourse via its association with the gender or class assigned. This reference-tracking device is found to be present in a large

variety of languages such as Archi, Swahili, and Yimas. Next, in a switch-reference system, the verb of a dependent clause is morphologically marked to indicate whether or not the subject of that clause is the same as the subject of its linearly adjacent, structurally related independent clause. If both subjects are co-referential, an SS (Same Subject) marker is used; otherwise, a DS (Different Subject) marker is employed. Switch-reference is found in many of the indigenous languages spoken in North America, the non-Austronesian languages spoken in Papua New Guinea, and the aboriginal languages spoken in Australia. It has also been found in languages spoken in North Asia and Africa. Somewhat related to the switch-reference system is the switch-function system. By switch function is meant the mechanism that tracks the reference of an NP across clauses in a discourse by means of verbal morphology indicating the semantic function of that NP in each clause. This system is found in a wide range of languages, including English, Dyirbal, and Jacaltec. Finally, there is the inference system. In this system, reference-tracking in discourse is characterized by (a) the heavy use of zero anaphors, (b) the frequent appeal to sociolinguistic conventions, and (c) the resorting to pragmatic inference. This mechanism is particularly common in East and Southeast Asian languages like Chinese, Javanese, and Tamil. Of the four reference-tracking devices mentioned above, the first is considered to be lexical in nature, the second and third, grammatical in nature, and the fourth, pragmatic in nature (see, e.g., Huang, 2000a and references therein).

Grammatical versus Pragmatic Approaches

With regard to intrasentential anaphora, two main types of analysis can be identified: (a) grammatical including syntactically oriented, semantically oriented, and a mixture of syntactically and semantically oriented, and (b) pragmatic.

Gramatical

Central to the various grammatical analyses is the belief that anaphora is largely a syntactic and semantic phenomenon, and as such reference must be made to conditions and constraints that are essentially syntactic and semantic in nature. This approach is best represented by Chomsky's (1981, 1995) binding theory and Reinhart and Reuland's (1993) theory of reflexivity within the principles-and-parameters theory and its minimalist descendant in the tradition of generative grammar. In addition, a current development in the grammatical analysis of anaphora and binding is to abandon all the conditions that are specific to binding and reduce them to elementary, general, and independent principles of the computational system of language within Chomsky's minimalist program (see, e.g., Safir, 2004; Hicks, 2009; Rooryck and Wyngaerd, 2011; especially Reuland, 2011).

Chomsky distinguishes two types of abstract features for NPs: anaphors and pronominals. An anaphor is a feature representation of an NP that must be referentially dependent and that must be bound within an appropriately defined minimal syntactic domain; a pronominal is a feature representation of an NP that may be referentially dependent but that must be free within such a domain. Interpreting anaphors and pronominals as two independent binary features, Chomsky hypothesizes that one ideally expects to find four types of NP in a language – both overt and nonovert – see Table 1.

Table 1 Chomsky's typology of NPs

	Overt	*Empty*
a. [+anaphor, −pronominal]	reflexive/reciprocal	NP-trace
b. [−anaphor, +pronominal]	pronoun	pro
c. [+anaphor, +pronominal]	–	PRO
d. [−anaphor, −pronominal]	Name	wh-trace

Of the four types of NPs listed in Table 1, anaphors, pronominals, and r- (referential-) expressions are subject to binding conditions A, B, and C, respectively (see Table 2).

Binding is defined on anaphoric expressions in configurational terms, appealing to purely structural concepts like *c-command*, *government*, and *locality*. The binding theory accounts for the distribution of anaphoric expressions in Table 3. It is also applied to empty categories: *NP-trace*, *pro*, and *wh-trace*. It has even been extended to analyzing VP-ellipsis and switch-reference, but that work will not be surveyed here.

In contrast to Chomsky's 'geometric,' syntactic analysis, the semantically based approach maintains that anaphora is subject mainly to semantic constraints. Consequently, it can be explained in semantic terms. Under this approach, binding is frequently defined in terms of argument-structure.

On Reinhart and Reuland's view, reflexivity is not a property of NPs, but a property of predicates. The binding theory is designed not to capture the mirror-image distribution of anaphors and pronominals, but to regulate the domain of reflexivity for a predicate. Putting it more specifically, what the theory predicts is that if a predicate is lexically reflexive, it may not be reflexive-marked by a morphologically complex SELF anaphor (e.g., *zichzelf* in Dutch, *se stesso* in Italian, and *zibun-zisin* in Japanese) in the overt syntax. And if a predicate is not lexically reflexive, it may become reflexive only via the marking of one of its co-arguments by the use of such an anaphor (see Tables 4 and 5).

There are, however, considerable problems with both versions of the binding theory cross-linguistically. Regarding Chomsky's theory, the distribution of reflexives violates binding condition A in both directions: on the one hand, a reflexive can be bound outside its local syntactic domain (so-called long-distance reflexive), as in Chinese, Icelandic, and Tuki; on the other, it may not be bound within its local domain, as in Dutch and Norwegian. Binding condition B is also frustrated, for in many of the world's languages (such as

Table 2 Chomsky's binding conditions

A. An anaphor is bound in a local syntactic domain.
B. A pronominal is free in a local syntactic domain.
C. An r-expression is free.

Table 3 Anaphoric expressions

a. Handel$_1$ admired himself$_1$.
b. Handel$_1$ admired him$_2$.
c. Handel$_1$ admired Handel$_2$.

Table 4 Reinhart and Reuland's binding conditions

A. A reflexive-marked syntactic predicate is reflexive.
B. A reflexive semantic predicate is reflexive-marked.

Table 5 Reinhart and Reuland's typology of overt NPs

	SELF	*SE*	*Pronoun*
Reflexivizing function	+	–	–
Referential independence	–	–	+

Danish, Gumbaynggir, and Piedmontese), a pronominal can be happily bound in its local syntactic domain. Next, given Chomsky's formulation of binding conditions A and B, it is predicted that anaphors and pronominals be in strict complementary distribution, but this predicted complementarity is a generative syntactician's dream world. Even in a 'syntactic' language like English, it is not difficult to find syntactic environments where the complementarity breaks down. Finally, even a cursory inspection of languages like English, Japanese, and Vietnamese indicates that binding condition C cannot be taken as a primitive of grammar.

Next, when we move to Reinhart and Reuland's analysis, we find that in the first place, cross-linguistic evidence has been presented that marking of reflexivity is not limited to the two ways they have identified. In addition to being marked lexically and syntactically, reflexivity can also be indicated morphologically. Secondly, more worrisome is that the central empirical prediction of the reflexivity analysis, namely, only a reflexive predicate can and must be reflexive-marked, is falsified in both directions. On the one hand, a predicate that is both syntactically and semantically reflexive can be nonreflexive-marked; on the other, a nonreflexive predicate can be reflexive-marked.

As mentioned above, a current development in the grammatical analysis of anaphora and binding is to eliminate all the conditions that are put forward specifically for binding such as Chomsky's binding conditions A, B, and C, discussed above, and to reduce these specific conditions to elementary, general, and independent principles of the computational system of language within Chomsky's minimalist program. For example, based mainly on the study of a range of Germanic and Romance languages, Reuland (2011) argues that anaphoric dependencies and their (substantial) cross-linguistic variations (in these languages) can be derived naturally by the interaction of the lexicon, syntax, semantics, and discourse components of the language system, which reflect the cognitive capacities and design of language.

This new development constitutes an important step forward in our understanding of anaphora and binding. Firstly, from a theoretical and methodological point of view, to account for anaphora and binding in terms of some elementary, general, and independent principles of Chomsky's minimalist program is much preferable to explaining them by means of some ad hoc, local conditions that are stipulated specifically for them. Secondly, while their focus is still on the syntax and semantics of anaphora and binding, the latest generative analyses of the type exemplified by Reuland (2011) allow nongrammatical or pragmatic factors to play a role.

On the other hand, however, these accounts are not without problems of their own. Again, take Reuland (2011) as an example. Theoretically and methodologically, Reuland's analysis still suffers from containing too many rules, conditions, and principles. In other words, the theoretical machinery is not parsimonious enough. Next, from an empirical perspective it is unclear to what extent Reuland's account can extend to languages other than the Germanic and Romance ones he has examined. For example, within Reuland's framework, the syntactic binding of a morphologically simplex SE-anaphor (e.g., *zich* in Dutch, *ziji* in Chinese, and *caki* in Korean) needs to enter an *A-chain* (argument-chain) that is created by movement. In order for an SE-anaphor to enter an A-chain, structural Case must be checked, which is achieved via the inflectional system of a language. While this analysis works for a Germanic (such as Dutch) and/or Romance language (such as French), it does not apply to, e.g., Chinese, because Chinese is a language that lacks any inflectional mechanism. Consequently, given that in Reuland's system, no structural Case checking means no A-chain, binding of an SE-anaphor in a language like Chinese has to be ruled out in narrow syntax (but allowed in pragmatics).

Pragmatic

Encouraging progress in the study of anaphora and binding in the last two decades has been the development of pragmatic approaches, the most influential of which is the (revised) neo-Gricean pragmatic theory of anaphora constructed by Levinson (1987, 2000) and Huang (1991, 1994/2007, 2000a,b, 2007, 2010a,b; see also Chiou and Huang, 2010). The central idea underlying this theory is that anaphora including binding is largely pragmatic in nature, though the extent of anaphora being pragmatic varies typologically. Consequently, anaphora can largely be determined by the systematic interaction of some general neo-Gricean pragmatic principles such as Levinson's (2000) Q- (Quantity-) ('Don't say less than is required/What is not said is not the case'), I- (Informativnes-) ('Don't say more than is required/What is generally said is stereotypically and specifically exemplified'), and M- (Manner-) ('Don't use a marked expression without reason/What is said in a marked way conveys a marked message') principles, depending on the language user's knowledge of the range of options available in the grammar, and of the systematic use or avoidance of particular anaphoric expressions or structures on particular occasions. **Table 6** is a revised neo-Gricean pragmatic apparatus for anaphora.

Table 6 Huang's revised neo-Gricean pragmatic apparatus (simplified)

i. The use of an anaphoric expression x I-implicates a local co-referential interpretation, unless (ii) or (iii).
ii. There is an anaphoric Q-scale ⟨x, y⟩, in which case the use of y Q-implicates the complement of the I-implicature associated with the use of x in terms of reference.
iii. There is an anaphoric M-scale {x, y}, in which case the use of y M-implicates the complement of the I-implicature associated with the use of x in terms of either reference or expectedness.

Needless to say, any interpretation generated by the neo-Gricean pragmatic mechanism in **Table 6** is subject to the general consistency constraints applicable to Gricean conversational implicatures. These constraints include world knowledge, contextual information, and semantic entailments.

There is substantial cross-linguistic evidence to show that, empirically, the neo-Gricean pragmatic theory of anaphora is more adequate than both a syntactic and a semantic approach. Consider, for example, Chomsky's binding conditions, as in **Table 2**, and its paradigmatic illustrations, as in **Table 3**. On the neo-Gricean account, Chomsky's binding conditions B and C can be reduced to pragmatics. In somewhat simplified terms, this can be achieved in the following way. If binding condition A is taken to be either grammatically constructed (as in the English-type, syntactic languages) or pragmatically specified (as in the Chinese-type, pragmatic languages), then binding condition B is the direct result of the application of the Q-principle. Given this principle, the use of a semantically weaker pronoun where a semantically stronger reflexive could occur gives rise to a conversational implicature that conveys the negation of the more informative, co-referential interpretation associated with the use of the reflexive, as in the b sentence in **Table 3**. By the same reasoning, binding condition C can also be eliminated. Wherever a reflexive could occur, the use of a semantically weaker proper name Q-implicates the nonapplicability of the more informative, co-referential interpretation associated with the use of the reflexive. This is exactly what has happened in the c sentence in **Table 3**. Furthermore, the revised neo-Gricean pragmatic theory can provide an elegant account of many of the anaphoric patterns that have embarrassed a generative analysis such as the cases where a pronoun is bound in its local syntactic domain. It can also accommodate examples like (3) and (6), which fall outside the scope of Chomsky's binding theory. In the case of long-distance reflexivization, the concept of logophoricity can be invoked to explain why such a marked anaphoric expression is used. (The phenomenon whereby the perspective or point of view of an internal protagonist of a sentence or discourse, as opposed to that of the current, external speaker, is being reported by utilizing some morphological and/or syntactic means. The technical term 'perspective' is intended to include words, thoughts, knowledge, emotion, perception, and space-location. Logophoricity is commonly encoded by a logophor or logophoric expression. It is largely a pragmatic phenomenon.) By logophoricity is meant the phenomenon whereby the 'point of view' of an internal protagonist of a sentence or discourse, as opposed to that of the current, external speaker, is being reported using some morphological and/or syntactic means. The expression 'point of view' is employed here in a technical sense and is intended to encompass words, thoughts, knowledge, emotion, and perception (see, e.g., Huang, 1991, 1994/2007, 2000a, 2002; see also Hagège, 1974; Clements, 1975). This use of long-distance reflexives is accountable in terms of the M-principle. Since the grammar allows the unmarked regular pronoun to be employed to encode co-reference, the speaker will use it if such a reading is intended, as in the Icelandic example (18a) (cited in Huang, 2000a: 227) (INDIC = indicative mood, SBJV = subjunctive mood). On the other hand, if the unmarked regular pronoun is not used, but the marked long-distance reflexive is employed instead, then an M-implicature will be licensed. The implicature is that not only co-reference but logophoricity as well is intended by the speaker. This is the case with the Icelandic example (18b).

18. a.	Jon	veit	að	Maria	elskar	*hann*
	John	knows-INDIC	that	Mary	loves-INDIC	him
	'John$_1$ knows that Mary loves him$_1$.'					
b.	Jon	segir	að	Maria	elski	*sig.*
	John	says-INDIC	that	Mary	loves-SBJV	self
	'John$_1$ says that Mary loves self$_1$.'					

No another correlation here. If relevant, the choice between regular pronouns on the one hand and logophoric long-distance reflexives on the other is correlated with that between indicative and subjunctive mood in the embedded clause. The use of a regular pronoun tends to go with that of indicative mood, as in (18a); the employment of a logophoric long-distance reflexive tends to go with subjunctive mood, as in (18b). This correlation is a reflection of a semantic/pragmatic choice made by the external speaker about the responsibility he or she assumes for the truthfulness of what he or she is reporting. If a regular pronoun and indicative mood are used, it indicates that the speaker asserts that the report is true. On the other hand, if a logophoric, long-distance reflexive and subjunctive mood are deployed, it shows that the speaker does not take responsibility for the truth of the report. More recently, a generalized, unified pragmatic analysis of the switch-reference system in Amele and logophoric verbal suffixation in Gokana has been successfully made in terms of the neo-Gricean pragmatic theory (see, e.g., Huang, 2010c). Finally, the revised neo-Gricean pragmatic theory can also be extended to provide an account of discourse anaphora in naturally occurring conversations (see, e.g., Huang, 1994/2007, 2000a, 2000b).

Next, from a conceptual point of view, the revised neo-Gricean pragmatic theory of anaphora has important implications for current linguistic theorizing. One major implication is that the theory forces a radical rethink of some of the current claims about the nature of grammatical rules and the way in which they interact with pragmatic principles. In the first place, many grammatical rules underlying anaphoric universals such as Chomsky's binding conditions are general, violable tendencies rather than absolute, exceptionless restrictions. Secondly, these rules are not something *sui generis*, but rather have their origins in language use. In other words, they are best seen as, to use Levinson's

(1987) metaphor, 'frozen pragmatics' – the outcome of a gradual, diachronic process from utterance-token-meaning via utterance-type-meaning to sentence-type-meaning. This, of course, does not mean that these rules as they are today are not part of the grammar. On the contrary, they are and as such they should be dealt with in the grammar. But the point is that if they are the result of a historical grammaticalization process, they can no longer be held as evidence for a biologically preprogrammed human linguistic faculty. Thirdly, pragmatics and syntax are interconnected in regulating anaphora and binding, though they are distinct levels and modes of linguistic explanation. The interface between pragmatics and syntax may in general be summarized in a Kantian apothegm: pragmatics without syntax is empty; syntax without pragmatics is blind. Furthermore, the extent to which pragmatics and syntax interact varies typologically. There exists a class of languages (such as Chinese, Japanese, and Korean) where pragmatics plays a central role which in familiar European languages (such as English, French, and German) has hitherto been alleged to be played by the grammar. In these pragmatic languages, many of the constraints on anaphora are primarily due to principles of language use rather than rules of grammatical structure. From a diachronic viewpoint, languages seem to change from being more pragmatic to more syntactic; from a synchronic perspective, different languages may simply be at different stages of this evolution.

A second major ramification the revised neo-Gricean pragmatic theory of anaphora has is concerned with current thinking about important issues such as universals, innateness, and learnability. While a pragmatic approach to anaphora such as ours does not entirely contradict Chomsky's innateness hypothesis, the fact that so many anaphoric processes in such a wide variety of geographically, genetically, and typologically distinct languages can be explained as learnable on the basis of language use does undermine Chomsky's claim to the universality of universal grammar and decreases the plausibility of his innateness hypothesis. This is because anaphora as such can no longer be taken to be mere instantiations of human mental templates. There are aspects of anaphoric universals that clearly are of a grammatical nature; there are also aspects of anaphoric universals that are equally clearly of a pragmatic nature. Put in a slightly different way, anaphoric universals are the product of both nature and nurture. The challenge before the linguist is to work out what are the grammatical rules and what are the pragmatic principles precisely, what is the relationship between them, and how they interact with each other.

It is encouraging that recent developments in generative grammar seem to be moving toward the position of the pragmatics–syntax interface being advocated here. Given that within Chomsky's minimalist program, the syntax/computational system is neither a phonological nor a semantic component, a large amount of current syntactic explanation has to be shifted to the logical form and phonological form interfaces. As a result, syntax has inevitably to interact with semantics and pragmatics in a much more extensive way to link it to the mental world of cognition (see, e.g., Chomsky, 1995). This holds, of course, for the study of anaphora, as we have already seen in Reuland (2011). These new developments will open the way for a more interactive approach between the I- (internalized and intensional-) and E- (externalized and extensional-) models of language study (see, e.g., Chomsky, 1995). It seems unlikely that we can provide a satisfactory answer to what Chomsky has referred to as Humboldt's problem and as (a special case of) Plato–Russell's problem without even trying to tackle Descartes's problem. In other words, the full understanding of the nature and ontogeny of our system of knowledge of language appears to be partially dependent on a better understanding of the (creative) use of that knowledge. This is, no doubt, the case for anaphora and binding too.

Anarchism

Maple Razsa, Colby College, Waterville, ME, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Anthropology's relationship with anarchism is complex and multivalent because anarchism is at once (1) a revolutionary tradition that sometimes draws on ethnographic research in developing its critique of contemporary society; (2) a theoretical orientation that has played a significant, if largely unacknowledged, role in the development of anthropology; (3) a form of social organization characteristic of societies without a state, including a great number studied by ethnographers and archaeologists; and (4) more recently, a set of antiauthoritarian principles and practices that have been integral to global social movements that have themselves become objects of ethnographic study.

Introduction

The sustained – if largely unacknowledged – relationship between anthropology and anarchism is not easily characterized. Peter Kropotkin, perhaps the most important anarchist thinker, personifies the complexity and multivalence of this relationship. Born a Russian nobleman, Kropotkin renounced his title and became a committed revolutionary, living much of his life in exile. Writing for the 1910 Encyclopedia Britannica, he provides one of the more enduring definitions of anarchism:

> (from the Greek, ἀν, and ἀρχή, contrary to authority) principle or theory of life and conduct under which society is conceived without government – harmony in such a society being obtained, not by submission to law, or by obedience to any authority, but by free agreements concluded between the various groups, territorial and professional, freely constituted for the sake of production and consumption as also for the satisfaction of the infinite variety of needs and aspirations of a civilized being. (p. 914)

In developing this understanding of anarchism, Kropotkin drew on his own zoological, geographic, and ethnographic observations in the Russian Far East. In challenging the dominant social Darwinism of his day – especially the emphasis on competition (e.g., 'survival of the fittest'), which Kropotkin felt reinforced support for the capitalist system – he stressed the crucial role of mutual aid in survival (1902). Since he understood anarchism not only as a potential future order but also as a long-standing human tendency, he drew on examples of existing and historic stateless societies – especially from the emerging discipline of anthropology – in elaborating his theory of a social order without state authority. To further complicate the relationship between these traditions, during Kropotkin's exile in England, he came to have a strong influence on Alfred Radcliffe-Brown, the founder of modern British anthropology (Perry, 1975). In fact, the influence of anarchist ideas, if rarely appreciated, is a thread woven through the history of anthropology.

Kropotkin thus provides an initial glimpse into anarchism and its varied intersections with anthropology. Anarchism is at once (1) a revolutionary tradition that sometimes draws on ethnographic research in developing its critique of contemporary society; (2) a theoretical orientation that has played a significant, if largely subterranean, role in the development of anthropology; (3) a form of social organization characteristic of societies without a state, including a great number studied by ethnographers and archaeologists; and (4) more recently, a set of antiauthoritarian principles and practices that have been integral to global social movements that themselves have become objects of ethnographic study. To date, there is a complex interaction between anthropology and these different facets of anarchism. Before examining this interaction in more detail, it is necessary to have in mind the history and key principles of anarchism as a political movement.

The Anarchist Revolutionary Tradition

Classical Anarchism

Many readers will associate anarchy – the lack of authority, especially state authority – with disorder, violence, and chaos – that is, either with the breakdown of established order or with an era preceding the emergence of the state, what Thomas Hobbes called the "natural condition of mankind." Second, some will call to mind bomb-wielding terrorists bent on bringing about just such a collapse of ordered society. These apocalyptic images are not surprising; 'anarchist' and 'anarchy' were deployed as epithets – including against the most radical and antiauthoritarian elements of the English Civil War and French Revolution – long before Pierre-Joseph Proudhon affirmed them as a self-description in *What Is Property?* (1840). Although earlier movements embraced similar political goals and practices – including the seventeenth-century English 'Diggers' – a broad-based and self-consciously anarchist movement first developed within the International Workingmen's Association (The First International, 1864–72). During these years, anarchists consolidated as a distinct bloc within the broader workers' movement. Although they largely shared with communists and socialists the goal of socialism, anarchists differed sharply over how to achieve radical political transformation. The storied debates between Marx and Bakunin crystallized these differences – differences that continue to define these distinct radical traditions – and foretold the schism that would end the First International. First, Bakunin objected to Marxists' revolutionary means: seizing state power and using that power to direct radical social change. Kropotkin

summarized anarchists' (prescient) fears about the Marxist approach when he wrote that to hand over

> to the state all the main sources of economical life – the land, the mines, the railways, banking, insurance, and so on – as also the management of all the main branches of industry, in addition to all the functions already accumulated in its hands (education, state-supported religions, defense of territory, etc.), would mean to create a new instrument of tyranny. State capitalism would only increase the powers of bureaucracy and capitalism. (1910: p. 914)

Second, anarchists challenged the preeminence of the proletariat in Marxist analysis, which posited that only the industrial working class – at once utterly dispossessed and absolutely integral to capitalism – was positioned to act as the subject of revolutionary activity. Bakunin, in contrast, asserted that outrage against the contemporary order came from many quarters, and the movement also should embrace the most excluded, including the peasants and the *lumpenproletariat* (the unemployed, common criminals, slum dwellers, scavengers, etc.), the very populations that Marx dismissed as secondary, or worse, counterrevolutionary (Avrich, 1988: pp. 7–13). The perceptiveness of his critiques aside, Bakunin was himself a veteran conspirator, often acting in a manner fundamentally at odds with antiauthoritarian principles. What is more, although these key anarchist figures – and their theoretical differences with Marx – are useful signposts in narrating the history of the anarchist movement, and distinguishing it from its primary revolutionary rival, one should not conflate anarchist movements with their most prominent authors and activists. Nearly all Bakunin's ideas, for example, were drawn from the practices of the anarchist struggles of their day (Marshall, 2010) and these anarchist thinkers were primarily pamphleteers and moralists rather than theoretical philosophers (Graeber, 2008: p. 211).

Although these strategic differences are significant in themselves, they also point to a fundamental difference between Marxist and anarchist approaches to politics. There were (and continue to be) a great variety of anarchist factions – including Mutualists, Anarcho-Syndicalists, Libertarian Communists, Anarcho-Pacifists, Individualists, Anarcho-Naturists, Green Anarchists, Insurrectionists, and Primitivists – but most shared an attitude toward radical change that is better characterized as a commitment to certain principles rather than a specific utopian goal, a commitment to means rather than ends. Anthropologists and historians of anarchism generally have identified these core principles as including autonomy, decentralized organization, direct democracy, antiauthoritarianism, and mutual aid. In other words, rather than being familiar with canonical texts, or acting as acolytes of key figures, as has often been the case for Marxists (e.g., Leninists, Maoists, Trotskyites), anarchists have exhibited "an adherence to a set of principles that guides much of anarchism and provides connections among its strains" (Angelbeck and Grier, 2012: p. 551).

Spain and the Violent Demise of Classical Anarchism

Popular and broad-based anarchist organizing reached its apotheosis in 1930s Spain – and this period is often cited by anarchists for the glimpse it provides of an anarchist order in an industrialized society. Already better organized and more numerous than movements elsewhere in Europe, Spanish anarchism blossomed during the Civil War – in fraught alliance with other social forces resisting General Franco's fascist rebellion against the republic. In the countryside, especially impoverished Andalusia, peasants embraced insurrectionary anarchism, seizing control of their pueblos to establish autonomous communes, destroy the power of the church and redistribute the land. By 1937 the anarchist labor federation, the Confederación Nacional del Trabajo, had more than 2 million members. In the industrialized Northeast, especially around Barcelona, these anarcho-syndicalists seized control of the factories and ran much of the public infrastructure. In May of 1937, however, armed conflict broke out between anarchists and communists, who were backed by Stalin. By January of 1939 the anarchists were crushed and Franco's forces entered Barcelona.

Beyond armed defeat and violent repression – not only in Spain but elsewhere in fascist Europe as well as the United States – two major causes of anarchism's decline as a significant political force stand out. First, the Bolsheviks, emerging victorious from the Russian Revolution, established the highly disciplined, hierarchical, and centralized party as the preeminent model of twentieth-century militant organization. Second, despite the pacifism of many of its key thinkers, including Godwin, Proudhon, Kropotkin, and Tolstoy, anarchism had come to be tainted by the acts of the minority of adherents who championed the 'propaganda of the deed' – and who had successfully assassinated the heads of state of Spain, France, and the United States in an effort to spark a broader social revolution.

Anarchism as Theory

> It is said that the histories of peoples who have a history is the history of class struggle. It might also be said, with at least as much truthfulness, that the history of peoples without history is the history of their struggle against the State. (Clastres, 1987: p. 218)

Stateless Societies and Anarchist Theory

Although the anarchism of the international movements of the nineteenth and early twentieth centuries cannot, of course, be conflated with modes of life of communities living without states – those known as primitive peoples in early anthropology – there has been a dynamic interplay between the antiauthoritarian ideas and practices developed by revolutionary anarchism and the anthropological study of stateless societies. Radcliffe-Brown, for example – a figure anthropologists more likely think of in relation to colonial anthropology – was known as 'Anarchy Brown' during his student days at Cambridge (Stanner, 1968: p. 287). By the time he was established as the founder of political anthropology, however, he had recanted anarchism and espoused a decidedly more moderate politics. As Perry argued, anarchist ideas – Kropotkin's in particular – nevertheless profoundly influenced Radcliffe-Brown and helped to set the tone of British social

anthropology during the first half of the twentieth century (1975: p. 61). Radcliffe-Brown's emphasis on mechanisms for maintaining order and social harmony in stateless communities – especially community centered sanctions, like avoidance or the withdrawal of reciprocity, rather than law – reflected the theoretical influence of anarchist ideas (Goody, 2000: p. 5). In any case, Radcliffe-Brown's anarchist tendency was not simply a personal quirk. His intellectual rival, Evans-Pritchard, more commonly identified with a conservative and Catholic worldview, wrote that "The Nuer constitution is highly individualistic and libertarian. It is an acephalous state, lacking legislative, judicial and executive organs. Nevertheless, it is far from chaotic. It has a persistent and coherent form which might be called 'ordered anarchy'" (1940: p. 296). In part, the anarchist tendency in anthropological theorizing of this period can be seen as part of an agenda – one they shared with Kropotkin – to challenge social Darwinists' emphasis on competition. Malinowski, for example, in a rare acknowledgment of anarchist theory, noted that "Prince Peter Kropotkin was quite right in pointing out that mutual aid between individuals of a cooperative community is the dominant concept, while the struggle between the individuals for survival can not be applied to human societies as a whole" (1944: p. 143).

If anthropologists of this generation, the first to carry out field research, were keen to challenge social Darwinism, and its associated belief in evolutionary hierarchy – the theories dominant among the 'arm-chair' anthropologists who preceded them – they were nonetheless deeply committed to developmentalism. In other words, if for this generation Aborigines, the Nuer, and Trobriand Islanders were equally human, at least in biological terms, their social systems were viewed as more simple – in a word, primitive – than 'complex' modern societies. This developmentalism later would be systematized in Elman Service's classification of sociopolitical stages, which ran in ascending order of increasing population, specialization, and elaboration from band through tribe and chiefdom to the state (1963).

With his avowedly anarchist theorizing, Pierre Clastres offers a fundamental challenge to this implicit – and persistent – developmentalism within anthropology. Drawing on his fieldwork with the Guyaki (Aché) of Paraguay, Clastres (1987 [1974]) questioned the assumption that primitive societies *lack* a state and as such are archaic remnants of an earlier epoch of human development that – given sufficient time – eventually would generate a state. On the contrary, as seen in the epigraph above, Clastres argued that it was only due to the active effort of stateless peoples that hierarchy and inequality were prevented from emerging. To put it another way, if humans are to preserve their autonomy, they must collectively create, cultivate, and maintain a range of practices that actively avert, ward off, and refuse the emergence of authority. In a similar vein, Clastres questioned dominant ideas of 'subsistence,' which implied that hunter-gatherers were incapable of producing a surplus and therefore were living desperate, hand-to-mouth existences (see also Sahlins, 1972). Clastres' interventions have far-reaching implications for political theory, especially for some of the ways theorists have imagined human existence before statehood. By positing active, and at times self-conscious, hunter-gatherer resistance to hierarchy, he countered the Rousseauian notion of man's natural state of innocence (the myth of the noble savage); tribal peoples, far from innocent, are painfully aware of the dangers of, and strive to prevent, the emergence of political authority. Similarly, by arguing that hunter-gatherers lead lives of plenty – yet studiously avoid producing material surplus for fear that the concentration of surplus value would institutionalize inequality – Clastres refuted Hobbes' famous claim that life without a state is one of "continual fear and danger of violent death, and the life of man, solitary, poor, nasty, brutish, and short" (1651: p. XIII.9). As Harold Barclay, another anthropologist with open anarchist sympathies, summarized the matter in *People Without Government*, "I believe many anthropologists, in their own projection of personal and cultural values, have obstinately refused to apply the one truly clarifying term to these numerous societies which are without government and are, therefore, anarchies" (1982: p. 18). Although anarchist theory has been useful in challenging the implied lack or absence imputed to nonstate social entities, this tendency is difficult to avoid; indeed, it persists in the term anarchism itself.

Recently, a number of anthropologists and archaeologists, in the tradition of Clastres and Barclay, have more openly championed the potential and actual contribution of anarchist theory to better understanding existing and historical stateless communities. In *The Art of Not Being Governed: An Anarchist History of Upland Southeast Asia*, for example, James Scott offered a provocative rereading of the ethnographic and historic record of Zomia, a vast highland region stretching from Vietnam to North India (2009). He argued that peoples like the Mien in China and Hmong across Laos, Vietnam, and Cambodia, far from representing the remnants of prestate societies, embody creative responses to the formation of states in the agricultural lowlands. Rather than existing in a not-yet-state condition, they actively fled the consequences of state formation: slavery, conscription, taxes, forced labor, epidemics, and warfare. What is more, Scott argued, they developed a range of creative strategies to maintain their autonomy and resist the rise of centralized authority within their own communities. Similarly, in 'Anarchism and the Archaeology of Anarchic Societies,' Bill Angelbeck and Colin Grier (2012) focus on long-standing questions related to the unusual political structure of the Coast Salish region of the Pacific Northwest. They argued that anarchism makes possible fresh and more revealing interpretations of decentralized social networks, especially those that allow for complex intergroup relations while staving off the establishment of centralized political authority. As they concluded, "Simply put, societies without governments are anarchies. Given that, we propose that the rich intellectual tradition of anarchist theory and practice has something to offer those studying the material record of those anarchic societies" (Angelbeck and Grier, 2012: p. 568). Charles MacDonald, teasing out the epistemological implications of his decades of intermittent fieldwork with the anarchic Palawan of the Southern Philippines, argued that anthropologists must be more discerning in labeling a given community anarchist. He pointed out that some communities that are not characterized by state authority are anything but anarchist in their attitudes toward inequality. He nevertheless echoed other anthropologists of anarchist societies when he concluded that "Equality is constructed, an active process enforced by various means and by constant

effort. Egalitarianists do not just abstain from inequality, like they would from consuming alcohol or wearing T-shirts; they produce and actively maintain equality" (Macdonald, 2012: p. 59).

The relatively minor yet persistent anthropological engagement with anarchist theory, especially in relation to the tradition of studying 'stateless peoples,' can be explained by the unique insights it generates – and the ways it militates against ethnocentrism. Here, we can see a parallel to the way anarchist revolutionary movements have served as an important corrective against the reductionist tendencies – and ends over means orientation – that have plagued Marxist movements. Analogously, anarchist theory serves as an important corrective to the persistent developmentalism of anthropological theorizing.

Anarchist Prospecting in the Ethnographic Record

Before turning to the ethnography of anarchist social movements, it is important to note two other anarchist theoretical developments of interest for anthropologists. First, anarchists have continued to show interest in anthropology, much as Kropotkin did earlier, in part due to the very anthropological tradition of studying and theorizing social order among stateless people outlined previously. There is obviously a chasm separating anthropology as professionalized academic practice from anarchism as a revolutionary one, but the specific nature of how and why anarchists engage anthropology perhaps indexes some underlying affinities between the two traditions. Indeed, it is difficult to think of any engagement with anthropology by nonanthropologists that more closely approximates the core principles of anthropology, especially in its more critical and publicly engaged forms. In their survey of anarchist prospecting in the ethnographic record, Andrew Robinson and Simon Tormey (2012) outlined at least four main modes of engagement. First, anarchists draw on anthropology to generate critique, that is, to develop tools with which to denaturalize the present by revealing alternative forms of social organization. Second, they seek techniques for sustaining stateless relations as found among those peoples anthropologists have studied. In this, they rely precisely on the affirmative reversal of statelessness-as-a-lack evidenced in the above history of anthropological theorizing of nonstate social entities. Third, they draw on anthropology to develop reflexivity, to help recognize the contingency of their own beliefs, which makes possible dialogue with communities that have different ontologies and epistemologies. Finally, activists draw on ethnography to cultivate solidarity, especially with indigenous peoples, whom they see as embodying models of struggle for autonomy (Robinson and Simon, 2012).

Anarchist Critical Theory?

The second anarchist theoretical trend is of anthropological interest because it concerns those social theorists who have been among the most influential in the recent history of the discipline. Although anarchism has not been associated with high theory, especially in comparison with Marxism, there have been recent efforts to develop a body of critical theory informed by anarchism. Often under the heading of post-anarchism – the post implying not so much the overcoming of the anarchist tradition, but its resonance with poststructural and postmodern theorizing – this literature (Rousselle and Evren, 2011) has noted significant affinities between anarchism and the thought of Nietzsche, Lacan, Derrida, Foucault, Deleuze, and Rancière, among others. At times, this work has drawn on these theorists to critique reductionist or essentialist strains within anarchism, such as, for example, the Manichaean tendency within some strains of the anarchist movement to see the state as a mortal enemy rather than a social relationship. Defenders of anarchism are quick to point out, however, that there have always been critics internal to the anarchist tradition who have resisted these tendencies. In any case, postanarchism draws connections between anarchism and those (mainly French) theorists who are highly influential in contemporary anthropology. It is possible to draw such links, Morris argued, because Deleuze and Foucault, for example, have implicitly drawn on the anarchist tradition in developing their ideas (2005: p. 12). To further complicate any clear genealogy, Deleuze and Guattari extensively deployed Clastres' concepts, especially in developing their ideas of a nomadic war machine (Deleuze and Guattari, 1987: pp. 357–360). Finally there is a robust tradition of autonomist Marxist theory – nonparty and anti-authoritarian in orientation, largely popularized in the English-speaking world by Hardt and Negri – that is deeply resonant with anarchism and sometimes is drawn on in analyzing recent movements that are highly influenced by anarchism (Razsa and Andrej, 2012). This recent theoretical production is viewed skeptically in many anarchist quarters, however, confirming Graeber's claim that while "Marxism has tended to be a theoretical and analytic discourse … anarchism is an ethical discourse about revolutionary practice" (2009: p. 211). What is more, it is plausible that the recent 'anarchist turn' in critical theory has as its condition of possibility the dramatic rise of a new wave of anarchist inflected social movements over the past few decades.

The Ethnography of Anarchist Movements (and Actually Existing Anarchy)

Colored perhaps by an inherent antipathy between academic and anarchist practice, scholars often have been dismissive of anarchist-inspired revolutionary movements. Graeber attributed this scholarly hostility to the fact that anarchism does not have the same affinity with the academy that Marxism does. First, anarchism is critical of the notion of a revolutionary vanguard, a role that Marxist scholars often have felt they could play. What is more, anarchism – as primarily an ethical discourse about revolutionary practice – has fewer scientific pretensions than Marxism, which was developed as a theoretical and analytic discourse (Graeber, 2004). Historical research on Republican Spain is symptomatic of scholarly antipathy toward anarchism.

The Anthropology of Spanish Anarchism

Early historians of the Spanish Civil War viewed anarchism as highly moralistic in character, reflecting a millenarian fanaticism that, they argued, owed much to the Catholic

faith it condemned (Brenan, 1950). In *Primitive Rebels*, Eric Hobsbawm elaborated on this position, describing anarchism as "a form of peasant movement almost incapable of effective adaptation to modern conditions" (1965: p. 92). In short, for Hobsbawm as a lifelong communist, anarchism was the embodiment of the 'primitivism' and 'ritualism' typical of social movements lacking modern forms of party organization and discipline. Anthropologists conducting research in Spain, especially in communities deeply affected by anarchist uprisings, were the first to carry out field research on these movements. Evans-Pritchard's student, Pitt-Rivers, for example, worked in a pueblo nationally renowned as the rural 'cradle of anarchism.' On the basis of fieldwork conducted during Franco's reign, however, *People of the Sierra* (1954) is circumspect about the town's anarchist legacy, and when it does refer to the movement, it does little to challenge the dominant portrait of rural anarchism as archaic and millenarian. Jerome Mintz's *The Anarchists of Casas Viejas*, the first anthropological account of anarchists in their own words, humanizes these radicals in a way earlier studies do not (1982). Mintz made clear that scholars' belief in evolutionary hierarchies preemptively discredits anarchism – not only when it is practiced by Fourth World peoples but also when it is adopted by twentieth-century movements in Western Europe. He noted that,

> although Eric Hobsbawm wrote that he visited Casas Viejas in 1956 and spoke with the townspeople, his account is based primarily on a preconceived evolutionary model of political development rather than on data gathered in field research. The model scales labor movements in accord with their progress toward mass parties and central authority … Unfortunately his evolutionary model misled him on virtually every point. (Mintz, 1982: p. 271)

Despite Mintz's important intervention – and even though the revealing testimonies he gathered indicates he developed relationships of great trust with his informants – he also conducted research during the waning years of Franco's rule. One wonders what affect this had, if any, on anarchists' nearly universal recanting of their beliefs in the course of interviews with him. Maddox (1995), who also conducted research in Andalusia, provided a rich contextualization for anarchists' committed anticlericalism, focusing on the stripping and dynamiting of the historic churches during another rural uprising. Despite the subtlety of his analysis, Maddox's Gramscian approach produced some grating theoretical dissonance. Framing anarchist actions in terms of hegemony and counterhegemony is incongruous with movements that probably are better understood as fundamentally antihegemonic. Finally, these anthropologists of Spanish anarchism primarily focus on ideology – as reported in either hostile sources or recollected in different political circumstances.

The Ethnography of the Alterglobalization Movement

Within a few years of these debates about historical anarchism – and in the wake of the collapse of state socialism from 1989 to 1993 – anarchism would once again come to have a powerful grip on the leftist imagination, arguably usurping the place that Marxism held for earlier generations of radicals (Epstein, 2001). Indeed, anarchist-inflected movements soon would burst disruptively onto the international stage – and anthropologists would have the opportunity to study not just anarchist ideas but anarchist daily practices. The streams of antiauthoritarian practice that merged to precipitate this anarchist turn among social movements in the late 1990s were varied – including feminist, antinuclear, peace, Quaker, environmentalist, and autonomist tributaries (Maeckelbergh, 2009: pp. 13–21). In light of the history of the anthropology of anarchism and 'stateless peoples' outlined previously, however, it is telling that most participants of what came to be known as the global justice or alterglobalization movement – and which the media often insisted on calling antiglobalization – traced the origins of their movement to the 1994 indigenous Zapatista uprising in Chiapas, Mexico. The Zapatistas embodied an antiauthoritarian politics that drew, in part, on indigenous practices of self-rule – including local autonomy, *mandar obediciendo* (leading by following), and consensus decision making. As such they marked a departure from the statist orientation of most twentieth-century movements, which, if they were reformist, sought to pressure the state to implement changes on their behalf and, if they were revolutionary, sought to seize the state and use it as a means to implement radical change. What is more, the first global network of movements, People's Global Action (PGA), which facilitated the convergence of various strands of activism, developed from the Zapatista-initiated Second Intercontinental Encounter for Humanity and Against Neoliberalism. The PGA, in turn, organized the Global Action Days, most notably the 1999 Seattle protests against the World Trade Organization that brought the movement to broad public attention.

The wave of major protest mobilizations that became the most recognizable face of the movement – in Washington, Prague, Quebec, Genoa, Quebec, and Miami, among other cities – and the global networking that made them possible provided the context for a generation of anthropologists to conduct fieldwork with movements that seemed to embody the core principles of anarchism. While there were countless links between these mobilizations and movements in the Global South – including important founding roles within the PGA for the Brazilian Landless Farmers' Movement in Brazil and the Indian Karnataka State Farmers' Association, in addition to the Zapatistas – anthropologists studying this wave of direct action movements did so largely in North America and Europe (Juris, 2008; Graeber, 2008; Maeckelbergh, 2009; Razsa and Velez, 2010).

A number of scholarly and political trends made the ethnographic study of these movements especially attractive at this time, including disciplinary interest in globalization, resistance, and activist anthropology. Anthropologists argued, moreover, that the decentralized, practice-centered nature of these movements seemed particularly suited to ethnographic approaches – even as it posed new challenges. As Graeber puts it,

> If anarchism is not an attempt to put a certain sort of theoretical vision into practice, but is instead a constant mutual exchange between inspirational visions, antiauthoritarian attitudes, and egalitarian practices, it's easy to see how ethnography could become such an appropriate tool for its analysis … to tease out the implicit logic in a way of life, along with its related myths and rituals, to grasp the sense of a set of practices. (2008: pp. 221–222)

Or as Maeckelbergh asserted, "taking an ethnographic approach to the movement allows for the exploration of the actual decision-making practices already in place, which make visible the beginnings of an emerging democratic alternative" (2009: p. 5).

While ethnographic methods were well suited to the study of these everyday practices, it proved difficult to delimit one's object of study when the density and frequency of links in these decentralized networks could lead one almost anywhere – after all, the PGA's slogan was "we are everywhere!" As Maeckelbergh asked, echoing broader methodological challenges in studying globalization, "How can we do ethnography of a global network that is not clearly delimited in time and space and has not singular identity, adversary or goal?" (2009: p. 22). Some ethnographers responded to this methodological dilemma by situating themselves within particular activist nodes and following activists from these nodes as they engaged the broader network (Juris, 2008; Razsa, 2008), while others took the process of creating a globally networked movement itself as their object of study (Maeckelbergh, 2009). Beyond methodological dilemmas, ethnographic writing on these movements posed its own challenges, some of them more politicized instances of the representational crisis precipitated by the writing culture debates of the 1980s. As Graeber expressed it, "to employ standard narrative techniques and allow some individuals to typify others would be to employ exactly the logic of representation that the activist decision-making structures I was trying to describe were trying hardest to avoid" (2008: p. 14). Although nearly all anthropologists of alterglobalization practiced some form of engaged, activist, or militant ethnography, this did not mean they shied away from describing the limits, conflicts, and contradictions of this movement's attempts to organize in antiauthoritarian and decentralized ways, reflecting perhaps the vigorous, even ruthless, internal debates and inbuilt practices of critical reflection among participants.

Indeed, a common characteristic of ethnographies of this "movement of movements" has been a focus on what Maeckelbergh calls its "unglamorous side" (2009: p. 3), namely, the organizational and decision-making practices that made possible the dramatic protest actions and mass mobilizations that were the public face of the movement. Juris's *Networking Futures*, for example, details the concrete practices "through which decentered networking logics are produced, reproduced, and transformed within particular social, cultural and political contexts" (2008: p. 11). The forms these took varied, but they included affinity groups, spokes, and spokescouncils, which could be traced to the Spanish Civil War, although refracted through other struggles, especially the antinuclear and peace movements of the 1980s. Activists and ethnographers alike emphasized the ways that directly democratic decision making is prefigurative – that is, it models more egalitarian, participatory, and inclusive modes of self-rule here and now.

These claims to prefigure change – along with other key principles of the movement – including direct action, consensus, horizontality, and diversity – would seem to echo classic anarchist ideas, especially the central method of "building the new world in the shell of the old." Graeber makes the starkest claim for the anarchist character of the movement overall, calling anarchists the "heart of the movement, its soul; the source of most of what's new and hopeful about it" (2002: p. 62). In fact, there is some debate about whether these movements should be considered anarchist. Juris (2008) argued, for example, that even as principles previously associated with anarchism have become preeminent in the movement, many activists do not identify with the label, in part because of the multiple sources of antiauthoritarianism – including, in addition to anarchism, Zapatismo, autonomous Marxism, and ecological movements. What is more, ironically given that Juris was based in the historic anarchist stronghold of Barcelona, many Catalan activists resisted being pigeonholed as anarchists, especially because some anarchist formations were relatively sectarian. Razsa, though he conducted fieldwork primarily with self-declared anarchists in the former Yugoslavia, nonetheless found that it was at those moments when anarchism was expressed most clearly as a political and (sub)cultural identity, rather than a set of principles, that it became an obstacle to the practical implementation of those principles (Razsa, 2008). Finally, Juris highlighted that the emphasis on networking as a *norm* was deeply resonant with anarchist ethics, but this ethic dovetailed with broader cultural and social shifts associated with late capitalism and associated modes of networked communication and production, and themselves were not necessarily radical in nature. This convergence, especially with web-based communications and social media, may indicate why practices that are deeply resonant with anarchist principles seized the radical imagination at this time. They also help to explain why geographically dispersed movements have found nonhierarchical ways to coordinate.

Global Uprisings

Although the scale and intensity of major mobilizations associated with the alterglobalization movement declined during the mid- to late 2000s – especially in the United States following the terrorist attacks of 11 September 2001 – a new cycle of protest exploded through 2011 and 2012. Beginning first in Tunisia before spreading to Egypt and much of the Middle East, the Arab Spring inspired unrest elsewhere. The movement of the *indignados* took up the torch in squares across Spain, kindling US activists' desire to Occupy Wall Street and create protest encampments in hundreds of US cities. Israel, Greece, and Chile also saw major protest movements. If the targets of these protests, what they opposed, varied – corruption, dictatorship, austerity, and wealth inequality – their practices almost universally have involved the embrace of direct democracy. Many analysts therefore have seen these movements as responses to a fundamental crisis of representative politics and as embodying a radical alternative to liberal democracy. Interestingly, those anthropologists who researched the alterglobalization movement were at the forefront of research on these new movements, perhaps because they were well positioned to tease out the continuities and discontinuities between these protests and earlier struggles. They were joined by a new generation of anthropologists who, like the previous one, were swept up in these dynamic movements as participants as much as researchers (Juris and Razsa, 2012). Many of the debates that marked the alterglobalization movement emerged anew around the

dynamics of inclusion and exclusion, the quality of democratic practice, prefiguration versus efficiency, the legitimacy of forming demands or not, and perennial questions of property destruction and violence. If the globalization movement wove together various strands of existing activism, developing innovative ways of coordinating different constituencies in decentralized and nonhierarchical ways, these new protest movements, in part because of the deep financial crisis since 2008, brought in a much wider cross section of people, many with no previous experience with direct democracy and direct action. Although this lead to tensions around 'process' it also offered a new wave of participants a personal experience of collective action and antiauthoritarian decision making.

Actually Existing Anarchism

Although the ethnography of anarchism primarily has been concerned with stateless communities on the one hand, or radical social movements on the other, there is an emerging interest in what might be described as actually existing anarchism. In many ways, this notion returns us, once again, to Kropotkin who insisted that anarchism was not only a model for a better future, or a condition of some Edenic past, but a persistent tendency in all social relations. Colin Ward, the British housing and education activist, pioneered this kind of anarchist research and action, keenly discerning the ways that anarchist principles are already operative in the cracks and fissures of an otherwise hierarchical British society (1973). Graeber even argued that mutuality is the foundation of all sociability, because social relations are always undergirded by the assumption that anyone who is not actually an enemy can be expected to engage others – at least to an extent – on the principle of "from each according to their abilities" (2011: p. 96). In a related movement toward identifying extant forms of autonomous organization, radical migrant activists and theorists have developed an understanding of the 'autonomy of migration,' which looks at the already existing practices that migrant communities use to 'manage the border from below,' asking how these practices might be cultivated and expanded as a basis for expanding migrant power.

Conclusion

The dynamic and multivalent relationship between anthropology and anarchism has enriched both traditions. From the standpoint of anthropology, anarchism in its various guises – as militant tradition, theoretical provocation, prefigurative practice, or mode of living – productively has disrupted the discipline's assumptions, especially regarding teleology, temporality, and the state. Anarchism contributed to the dislodging of first evolutionist and then developmentalist assumptions – and with them certain strains of ethnocentrism. Anarchism – with its slogan 'another world is possible' – also reaffirms the fundamentally anthropological disposition that a great variety of social orders and ways of being human are possible; politics, therefore, always can be radically reimagined. In this spirit, anarchism may continue to catalyze a new political anthropology, even a return to anthropology at its best: The exploration of ways of being human that are at odds with what appears natural and inevitable from the vantage point of the present.

Abstract

The main question asked about ancestors by anthropologists is how the living define them, transform the dead into them, and use them to safeguard social and individual moralities. Ancestors are distinct from the mass of the dead: their descendants select and make them by mortuary rites. The selected deceased are linked to their descendant by descent and are usually those who hold a structurally important genealogical position as founders of family segments. Those not selected for ancestorhood join the generality of the dead and are soon forgotten. Ancestors are thought to dwell in a home of the dead, or near their descendants with whom they may communicate; they may punish if offended. The latter communicate with the ancestors by offerings of food or goods. They are remembered in genealogies or memorialized by graves or written monuments. Their importance tends to lessen in 'modern' societies in which kinship may be of little importance, and where Christianity, Islam, or other 'world' religions give more emphasis to deities and less to ancestors.

The study of beliefs and rites involving ancestors has long been a central anthropological concern. Many early anthropologists suggested that ancestral worship was the forerunner of all religions and devoted much time to building conjectural religious histories. Twentieth century anthropologists have devoted attention to the working of ancestral cults as aspects of wider religious systems and to their links to rights in property, succession to office, and cohesion of descent groups. The main questions asked include how the living define ancestors, transform the dead into them, and use them as guardians of morality and agents of social continuity.

The word 'ancestor' is often used as a synonym for 'the dead': but they should be distinguished – not all the dead are remembered and defined as ancestors. Those selected as ancestors provide a history memorializing certain events of the past that give significance to claims of the present. Defined ancestors may either actually have lived at a remembered time, may be given a place in a genealogy irrespective of the date of death, or may be invented so as to provide their believed descendants with history and identity.

The status of ancestor is given by a rite of transition performed by the living descendants of the deceased. Robert Hertz (1960) listed the three components of mortuary rites: the corpse, the mourners, and the soul. The functions of the rites are to dispose of the corpse; to remove the deceased from the immediate domain of the living and to transform him or her into an ancestor; to re-form the descent group of the deceased's living kin; and to ensure the continuity of the essential element of the deceased's human identity, the soul or some similar concept. The forms the rites take reflect the importance of the deceased: those for a king may be highly elaborate and last many months or years, for a respected elder be less so and take a few days, for a child be minimal and take only a few minutes (Huntington and Metcalf, 1979; Bloch and Parry, 1982).

The living decide which of the dead shall be transformed into ancestors. The key criterion is the link of kinship between a living group or person and an ancestor. Without that link the deceased is not an ancestor but merely a dead person and soon forgotten. To possess recognized ancestors gives the living descendants full identity and status; to lack them (as in the case of slaves in many societies) is to lack full status.

Several ancestral categories may be defined. For example, the Lugbara of Uganda (Middleton, 1960) distinguish the *ori*, a descent group's direct and renowned male patrilineal forebears, to whom are made ritual offerings; *oku-ori*, female *ori*, daughters of the patriline who, although they bore sons to other descent groups (by the rule of exogamy), are remembered as powerful women; and *a'bi*, the general mass of other dead members of a given clan. Only relatively few of the dead become *ori* and *oku-ori*, whereas the number of *a'bi* is beyond reckoning. The ancestors of other clans are of no concern and are merely *a'bi* without definition.

Ancestral categories may also depend upon the manner of death. The Akan of Ghana, for example (Fortes, 1959), distinguish three kinds of death: good death, the natural death of man or woman followed by a future in the land of the ancestors; bad death, due to evil behavior during life and a double death, first that in the living world and later within the land of the ancestors, whose inhabitants refuse to accept the deceased who is returned to the land of the living to linger as a bad and dangerous specter; and sudden death, as in war, childbirth, accident, or suicide – such a person is not buried properly in a clan cemetery but in the bush land and is then 'lost' as an ancestor.

Among the Chinese, as a third example, Confucianism makes a general distinction between the ancestors and the non-ancestral dead (Hsu, 1948; Ahern, 1973; Wolf, 1974). The former are men of strictly patrilineal descent groups, senior kinsmen with clearly recognized rights due from their descendants and obligations towards them. Women are not defined as ancestors, although they have been daughters, wives, and mothers to the ancestors of a particular descent group.

These cases show that whether individuals are defined as ancestors depends upon their kinship ties with their descendants, linked by mortuary rites and by inheritance of social position and property. Ancestors possess no independent status in themselves but are given it by their living kin.

Once made into ancestors, where they dwell and the nature of their relationships to their descendants vary from

one society to another. Christian cultures hold that claimed ancestors and other dead dwell either with the Deity in a heaven, a place of peace without further passing of time, and/or a hell, a place of punishment and atonement. The Akan peoples of Ghana hold that ancestors dwell in a land of the dead across a river, which has the same patterns of stratification and authority as that of the living. The Lugbara of Uganda consider that they dwell underground near their descendants' settlements, where they themselves have been buried. In virtually all religions ancestors are considered to be senior kin living apart from their descendants yet still linked by spatial propinquity and kinship interdependence. They are typically believed to see and hear their living kin, who as their juniors are unable to see or hear them except in unusual circumstances, such as their appearance as specters or when people are possessed by them.

Associated with the concept of ancestor is that of soul, linked to individual morality rather than to descent and kinship. The concept of soul was of great concern to early anthropologists such as Frazer (1911-15), Lévy-Bruhl (1927) and Tylor (1871), who coined the term 'animism' for the belief in souls attributed to all living things. Their views were essentially conjecture: more recently ethnographic research, including that on religion, has become based on detailed study of the beliefs and practices of particular cultures. For example, the Lugbara word *ori* is related to the word *orindi* (literally 'the essence of the *ori*') which might be translated as 'soul,' an element of the living that is not exterminated by death but which persists into the afterlife. Only men of full adult status have what might be called full souls; women who are the first-born of a set of siblings may be attributed souls if they acquire respected status before death, and it is they who become *oku-ori*. Other men and women lack souls or, more accurately, do not realize the potentiality of developing them, and it is they who are placed in the loose category of *a'bi*. Different societies order these concepts and elements in differing ways, but the basic factor is that of an individual's moral passage through life, the soul being that element that bestows him or her with morally responsible behavior.

Ancestors have to be remembered, usually by being listed in genealogies. Evans-Pritchard (1940) showed for the Nuer of the Sudan that the generational depth of genealogies reflects the width and composition of descent groups on the ground: the wider the group the more the number of generations needed to include all its members in a single genealogy. The identity of effective ancestors usually depends upon the recognition of a particular mode of descent (patrilineal, matrilineal, or cognatic) as the basis for local social organization. Genealogies are not, or only extremely rarely, historically accurate statements. There is typically a telescoping of generations so as to maintain the same depth of a genealogy over time; and in patrilineal systems, certainly, the exclusion of most women is usual as they do not exercise the same degree of authority as do men. The situation is different in those societies in which ancestors are memorialized in writing or on tablets (e.g., China and Mormon America); here the purpose may be to include all forebears by name irrespective of their immediate and active links to their descendants.

Terms commonly used in discussions of ancestors include 'ancestral spirits,' 'ancestral worship,' and 'ancestral cults,' that refer to the relationships between the living and their own ancestors. The beliefs and practices concerning ancestors nowhere form a distinct religion but rather a religious practice within a wider societal religion. This practice typically includes lineage and family rites, periodic rites on ancestral death days, and often annual rites for collectivities of a group's ancestors. Rites linked to the non-ancestral dead in general should not be included. Ancestors are virtually everywhere held to care for and protect their descendants; they may teach, criticize, and punish them for unfitting behavior. They may send sickness or other affliction to those who disobey their rules and wishes, and they are in general held to be conservative in their views and to represent an idealized stability and moral order. They may act on their own initiative or may be evoked by their descendants. The living may consult oracles or diviners, or interpret omens, to discover the identities and motives of specific ancestors concerned.

The living may communicate with their ancestors both by making verbal requests and by offering them food (often flesh and blood) and drink, commensality being a central act of kinship bonding. Offerings may be regular or made only when the ancestors show that they wish to receive them, at shrines of many kinds, from ancestral graves to special buildings, and may be simple and cursory or elaborate and long-lasting, depending on the ancestors' remembered status.

The term 'ancestral spirit,' used for those aspects of ancestors thought to come into direct contact with the living, is clumsy: ancestors and spirits are in their natures quite distinct. Ancestors have been among the living, who remember the more recent of them as individuals and understand their wishes and demands. Even if their individual personalities are in time forgotten, they represent human experience, skills, and sentiments, and are senior kin. They are used by the living both to maintain conservative authority and moral order and to help bring about orderly settlement of disputes. They provide and maintain the long-lasting stability of otherwise ever-changing and fluid descent groups. On the other hand, spirits are refractions of divinity, have never been living and so have no descendants: their natures and demands are different and may be beyond human understanding. The living can exercise a more immediate control over their ancestors by stressing their link as kin, than they can over spirits. Ancestors may act as unvarying custodians of order, unlike spirits which are by contrast individualistic, capricious, and unpredictable.

An important point is that of the persistence of beliefs in ancestors in the 'modern' industrialized world. The rites of invocation and appeasement of ancestors may lose importance for small-scale descent groups precisely as these lose importance in radically changing societies; ancestors are those who, when they lived, were important in the lives and continuity of their descent groups of the time. By being remembered and commemorated in ritual, they are objects of the group's memory of the past and its identity of the present. Ancestors used as mnemonic figures remain important, as do their material representations such as tombs and shrines. This is especially so in the case of those who in their lives were kings, sacred personages who embodied the identity and continuity of their kingdoms. Such royal ancestors are not only used as signs of memory by their genealogies: they are typically given

royal tombs that materially represent the past in the present and so act as centers of societal identity. In societies that accept Christianity, Islam, or other world religions, greater emphasis may be given to spirits: ancestors' powers are limited to their own descendants whereas those of spirits are typically held to affect all members of a society irrespective of their descent groups.

Ancient Egypt, Archaeology of

Marleen D Meyer and Stefanie Vereecken, KU Leuven, Leuven, Belgium

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The civilization of ancient Egypt flourished between 4000 BC and AD 395 along the banks of the River Nile. During the late nineteenth century the archaeology of this region started to take shape, originally focusing mainly on cemetery sites, but since the 1960s settlement sites have been increasingly excavated. Recent developments in the field of archaeometry are opening up new research perspectives for the study of the material culture.

The archaeology of ancient Egypt is concerned with the remains of prehistoric cultures (*c*.700 000–4000 BC), as well as predynastic and pharaonic civilization (*c*.4000 BC–AD 395) that flourished along the banks of the River Nile and further into the desert in an area that roughly corresponds with modern-day Egypt. Chronologically and geographically several delimitations are possible.

Chronology

The historic sequence of pharaohs is based on kings' lists, annals, and other documents that survived from ancient Egypt (**Table 1**; Redford, 1986). However, the division of ancient Egyptian history in 30 dynasties is based on the writings of the Egyptian priest Manetho, who wrote the *Aegyptiaca* (History of Egypt) in the third century BC. The original manuscript is not preserved, but passages were handed down by later authors. Egyptologists have added two more to Manetho's 30 dynasties: First, Dynasty 0 encompasses a series of rulers that preceded Narmer (now generally seen as the first king of Dynasty 1) and are buried in cemetery U at Abydos. During Dynasty 0, writing was known, but Egypt was not yet unified. The second is Dynasty 31, which refers to a short period between 343 and 332 BC when Egypt was a Persian satrapy for the second time in its history. These dynasties were grouped together by nineteenth-century Egyptologists into several larger periods when Egypt possessed a strong unified state (Old, Middle, and New Kingdoms) and intermediate periods, when central authority was waning for different reasons (First, Second, and Third Intermediate Periods). After the Third Intermediate Period follows the Late Period, which ends with Dynasty 31. Alexander the Great conquered Egypt in 332 BC, and the Macedonian dynasty that occupied the throne in Egypt after his death is referred to as the Ptolemaic Dynasty. In 30 BC Egypt became a Roman province until AD 395. Pharaonic civilization had already died a slow death through the spread of Christianity starting in the third century AD (Coptic Period) when Egypt was conquered by Arabs in AD 641.

Prehistory and the era immediately preceding and leading up to the pharaonic civilization – the Pre- and Early Dynastic Period – have received a greater attention from scholars since the 1980s, so much so that this has almost grown into its own discipline. However, the chronology of this period consists mainly of local site- or region-specific chronologies, and an all-encompassing study still remains to be made (Hendrickx, 2006). The beginning of the historical period of pharaonic Egypt is traditionally defined by the unification of Upper and Lower Egypt under the legendary King Narmer. However, the discovery in 1988–89 of the oldest hieroglyphic writing on jar labels in Tomb U-j at Abydos has pushed back the date of the origin of writing in Egypt about 150 years, thus also pushing back the start of the historical period when this is defined by the presence of writing (Dreyer, 1998).

Table 1 Chronological overview of ancient Egyptian history

Paleolithic Period	c.700 000 BP-7000 BC
Saharan Neolithic Period	*c*.8800–4700 BC
Predynastic Period	*c*.5300–3000 BC
Early Dynastic Period (Dynasties 1–2)	*c*.3000–2686 BC
Old Kingdom (Dynasties 3–8)	2686–2160 BC
First Intermediate Period (Dynasties 9–mid-11)	2160–2055 BC
Middle Kingdom (Dynasties mid-11–14)	2055–1650 BC
Second Intermediate Period (Dynasties 15–17)	1650–1550 BC
New Kingdom (Dynasties 18–20)	1550–1069 BC
Third Intermediate Period (Dynasties 21–25)	1069–664 BC
Late Period (Dynasties 26–31)	664–332 BC
Ptolemaic Period	332–30 BC
Roman Period	30 BC–AD 395
Egypt ruled from Byzantium	AD 395–641
Arab conquest of Egypt	AD 641

Geography

The Nile Valley is clearly defined by the natural environment: the Mediterranean Sea to the north, the First Cataract in the Nile to the south, and the desert to the east and west form clear natural buffers. In antiquity, the southern border of Egypt was generally located in the area of the First Cataract, near modern-day Aswan. At different periods of Egyptian history, this border moved further south to include large parts of Nubia in present-day Sudan north of Khartum. The eastern border also moved further east, especially during the New Kingdom, to incorporate parts of the Levant.

The Development of Egyptian Archaeology

While interest in the pharaonic culture was already cultivated by the ancient Greeks and Romans, and later reappeared during

the Renaissance, the scientific study of ancient Egypt in the west only took off in the beginning of the nineteenth century. The expedition of Napoleon to Egypt in 1798 and the resulting publication of the *Description de l'Égypte* in 24 volumes (1809–29) are generally considered to be the starting point for this. During the late eighteenth and early nineteenth centuries, several other descriptive works were published that documented the state of monuments throughout Egypt at that time, such as the *Denkmaeler aus Aegypten und Aethiopien* in 12 volumes (1849–59) produced by the Prussian expedition of Karl Richard Lepsius. Based on such publications, the study of ancient Egypt originally focused on philology rather than archaeology, with several scholars attempting to decipher the hieroglyphic script. This reached a breakthrough in 1822 when Jean-François Champollion outlined the basics of the system in his *Lettre à M. Dacier*. Even though around the same time major European museums such as the Louvre and the British Museum were starting to amass collections of ancient Egyptian antiquities, the excavation of these objects was not of a scientific nature. This started to change in 1859 when the Department of Antiquities was founded in Cairo by the French Egyptologist Auguste Mariette to regulate excavations throughout Egypt. While this institution was originally headed by a series of French Egyptologists, the Egyptians have directed it since 1953, and it still exists, albeit in a modified form. Since the revolution of 2011, this institution became its own ministry and was renamed as the Ministry of State for Antiquities (MSA). The MSA regulates excavations in Egypt both by foreign missions as well as Egyptian missions, oversees conservation projects, and is generally in charge of protecting Egypt's heritage.

Archaeology primarily lingered in the realm of treasure hunting until scholars such as William Flinders Petrie (1853–1942, the UK) and George Andrew Reisner (1867–1942, the USA) started to define methodological approaches in excavation during the late nineteenth century. Petrie was not only pioneering within the field of Egyptian archaeology itself, but his methods of seriation applied to Pre- and Early Dynastic Egyptian pottery were revolutionary for the field of archaeology in general (Petrie, 1901). Petrie also introduced the concept of stratigraphy into Egyptian archaeology. Reisner was influential for his methodological record keeping and documentation, describing for instance at length his principles for archaeological photography (Manuelian, 1992), and he was innovative in surveying techniques as well. Around the same time scholarly societies were being formed, mainly in Europe, that funded and supported archaeological fieldwork in Egypt, such as the Egypt Exploration Fund (presently still operating under the name Egypt Exploration Society) in the United Kingdom, which was founded by Amelia Edwards in 1882, and the Institut français d'archéologie orientale, which was founded in 1898 and is also still active to this day.

In the 1960s there was an international effort to salvage sites and monuments that were under threat by the rising water table of Lake Nasser, the artificial lake that formed as a result of the construction of the second High Dam at Aswan. Monuments in the south of Egypt and the Sudan were moved to higher grounds, sites were excavated, and some monuments were donated to museums in participating countries. This also led to Nubiology as a discipline.

In Egyptian archaeology, the focus has historically mainly been on funerary archaeology. Settlement archaeology did not seriously begin until the 1960s, a time when archaeological methodology also started to change under the influence of processual archaeology (a theoretical framework, which found its origins in the late 1950s). The reasons for this focus on funerary archaeology are outlined below. Presently, the study of the material culture is advancing rapidly with the application of techniques from the physical sciences.

Funerary Archaeology

The spectacular discovery of a cache of royal mummies (dating to the New Kingdom and later) in the Theban necropolis by the Abd el-Rasul family in 1870 set in motion the scientific exploration of this area in the late nineteenth century. The Valley of the Kings underwent more systematic exploration since then, which led to the discovery of the tomb of Tutankhamun in 1922 by Howard Carter. The latter provoked a wave of Egyptomania in the decorative arts that had not been seen since the expedition of Napoleon over a century earlier. In the meantime, Reisner had started systematic exploration of the Giza plateau – the necropolis of the kings and high officials of the Fourth Dynasty – and Petrie was working at Abydos in the tombs of the early Dynastic kings. A bit later, right before World War II, Pierre Montet had discovered royal tombs of the Twenty-first and Twenty-second Dynasty at Tanis in the Delta. Thus the tombs of many of the kings of the pharaonic civilization had been under investigation in the first half of the twentieth century.

In addition to royal tombs, necropoli of the general population were also being excavated, although often they too belonged to the elite rather than to commoners. Early twentieth century excavations at cemetery sites tended to cover vast surfaces with very little publication of the work afterward. An example of such an excavation is the work of John Garstang at the Middle Kingdom necropolis of Beni Hasan (Garstang, 1907). This practice has led to a paradox within the archaeological record of cemetery sites in Egypt, namely that while the surface areas that were excavated in the early days are exponentially larger than the surface areas that can be covered by modern-day techniques and methodology, the documentation of these old large-scale excavations does not live up to modern standards. Additionally, many of the original records are still locked away in museum cupboards or institute basements. Digital imaging and online publication of old excavation documentation, however, have recently started to open up many new research perspectives. A pioneering project in this regard is the Giza Archives Project at the Museum of Fine Arts in Boston (www.gizapyramids.org). At the core of the project is the aim to publish online all the photos, excavation diaries, drawings, plans, in short all the documentation that was produced by George Reisner during his excavations at Giza from 1902 to 1942. However, the project goes beyond that by aiming to include other sources of information on the site of Giza as well, and likewise reconstructs the site in 3D virtual reality.

Despite the fact that old records are not up to modern standards, this does not mean that the data from the old excavations should be disregarded all together, but rather that techniques should be applied to distill as much information

out of them as possible. A good example of the type of results that can be obtained by applying modern statistical analyses to old excavation data from cemeteries is Seidlmayer (1990). Methodical reexcavation of sites that were hastily dug through in the past, also proves to be rewarding, such as is clear from the reexcavation of the early Dynastic cemetery of Umm el-Qa'ab at Abydos by the German Archaeological Institute (Dreyer, 1998). Presently, cemetery sites are studied at a much slower pace and in an interdisciplinary way. Physical anthropologists, zooarchaeologists, botanists, geographers, etc., complement the team of Egyptologists and archaeologists, such as for instance at the site of at Hierakonpolis in Upper Egypt (www.hierakonpolis-online.org) or at Dayr al-Barsha in Middle Egypt (www.dayralbarsha.com). The latter also forms part of a recent trend in research of provincial sites, as does the Asyut Project (http://www.aegyptologie-altorientalistik.uni-mainz.de/139.php).

Settlement Archaeology

Settlement archaeology has developed at a much slower pace in the field of Egyptian archaeology than it has for instance in Near Eastern archaeology, where *tell* sites present accumulated layers of human occupation. There are several reasons for this. Firstly, there has been a bias in the research due to the overwhelming presence of well-preserved temples and tombs in Egypt. These monumental and generally elite constructions have drawn away attention from settlements during much of the nineteenth and early twentieth centuries, with some exceptions such as Deir el-Medina. It is only from the 1960s onward that serious research interest in ancient Egyptian settlements began, the pioneering project being the excavations of the Austrian Archaeological Institute of Cairo under the direction of Manfred Bietak at the site of Tell el-Daba' in the eastern Delta (www.auaris.at).

Secondly, settlements in the Nile Valley are generally badly, if at all, preserved due to the specific geographic situation. Settlements, located in the narrow strip of fertile land along the banks of the Nile, were subject to annual flooding, and were frequently built over in subsequent periods of Egyptian history, even until this day. Therefore, even if settlement remains are preserved, they are often very difficult to reach. This is especially true for organically grown settlements in the Nile Valley, the villages and towns that made up the backbone of the Egyptian landscape. A good analogy for the development of urbanization within these organically grown settlements is the game-playing model as presented by Kemp (2006). The best preserved example of an at least partially organically grown settlement in the Nile Valley is the site of Tell el-Amarna, the short-lived capital of Egypt during the reign of Akhenaton, which was built and subsequently abandoned between years 6 and 17 of his reign (www.amarnaproject.com). Although this city is an abnormality in itself, and large portions of it were laid out in a planned manner, the houses in between the official structures tend not to follow a preplanned layout.

There are also a number of settlements, however, that are not located within the Nile Valley itself, but immediately outside of it in the desert fringe, which have managed to escape the same fate. Such settlements are generally not organically grown, but rather (state) planned settlements that were built with a specific purpose in mind. Settlements of this type include workmen's villages to house workers of large building projects (e.g., at Deir el-Medina for the construction of the New Kingdom royal tombs in the Valley of the Kings, or at Heit el-Ghorab for the building of the Old Kingdom pyramids at Giza; www.aeraweb.org); pyramid towns where personnel were housed who were in charge of maintaining the mortuary cult of deceased kings (e.g., the Old Kingdom Khentkawes town at Giza, or the Middle Kingdom town of Lahun next to the mortuary complex of Senwosret II); and fortresses built to defend the borders of Egypt (e.g., the Nubian fortresses of Mirgissa, Shalfak, Uronarti, Buhen, and others which were mainly in use during the Middle Kingdom; or the fortress at Zawiyet Umm el-Rakham about 300 km west of Alexandria, built during the New Kingdom as a defense against the Libyans). Such planned settlements are usually laid out along an orthogonal plan, with modular living spaces of an identical or highly similar structure. While such settlements are better preserved in the archaeological record, they cannot be taken as type examples of an average ancient Egyptian town. The population of such settlements is also often not representative of an average population (concentrations of workmen or soldiers instead of families), and since food was often prepared outside such settlements and then delivered as finished meals to the workers, the material culture does not reflect what can be expected in organically grown towns. In areas further away from the Nile Valley, such as the oases in the Western Desert, and in particular in the Dakhla Oasis and Kharga Oasis, well-preserved settlements have also been found. These locations were of strategic importance for trade routes, and for instance at Balat/'Ayn Asil (Dakhla Oasis) an entire settlement evolved around the palace of local Sixth Dynasty governors, including an industrial area of potters' workshops (Soukiassian et al., 1990). The administration in this remote locality seems to have been remarkably similar to that of the residence in the Nile Valley, albeit on a more modest scale (Pantalacci, 2013).

Remote sensing, satellite imagery, and ground-penetrating radar are tools that are increasingly being used to try and remedy the lack of knowledge about organically grown settlements in the Nile Valley. But even if settlements can be located this way, the archaeological layers on top will often date to the Greco-Roman Period. To gather information about lower and older layers of occupation, traditional archaeological methods will need to supplement the data obtained through remote sensing.

Study of Material Culture

While during the first half of the twentieth century large collections of artifacts had already been excavated in Egypt, the analytical study of the material culture only seriously began with the publication of *Ancient Egyptian materials and industries* (Lucas, 1926). This remained for a long time the standard work of reference for Egyptologists and archaeologists in this field, and several revised editions appeared until 1962 with supplementary material added by John R. Harris. Over the last few decades a more multidisciplinary approach has been applied to different materials in the archaeological record, involving

scientific analytical techniques, which provide new insight into different technological and socioeconomic questions. This has led to the new standard work *Ancient Egyptian Materials and Technology* (Nicholson and Shaw, 2000), which forms a solid base for different aspects of the material culture and its technological aspects.

Pottery

In spite of the fact that pottery occurs in large quantities on every site in Egypt, there was no profound interest in the pottery of ancient Egypt until the mid-twentieth century. Although Petrie's methods of seriation applied to Pre- and Early Dynastic Egyptian pottery were revolutionary for the field of archaeology in general, his example was hardly followed and the most common practice on excavations in those days consisted of collecting only complete vessels or decorated ware without paying further attention to the identification of materials and their source of trade, nor to the physical characteristics of vessels to show their place in technological development.

A turning point came with the formation of the international group for the study of ancient Egyptian pottery, an initiative undertaken by Dorothea Arnold of the German Archaeological Institute in 1975. Here the foundation was laid for a new approach of pottery analysis and from then on, there has been a change in the emphasis of pottery analysis, with more attention being paid to disciplines such as fabric analysis and archaeometry. An important milestone in this evolution was the publication of *An Introduction to Ancient Egyptian Pottery* (Arnold and Bourriau, 1993), a pioneering work for the processing and description of pottery in the field. This publication pointed out the importance of the study of technology and fabric and introduced the Vienna System, a visual classification system for fabrics, which could be applied in the field. This system does not depend on petrological analysis of thin sections or other laboratory-based techniques, which are also necessary, but which are difficult to obtain because only few laboratories in Egypt offer the possibility for such analysis, and taking samples out of the country is forbidden. Despite these problems, archaeometry is also finding its way into pottery analysis as a subsequent step intended to test and refine the groupings of fabrics (e.g., Bourriau et al., 2000 for the petrographic analysis of New Kingdom pottery fabrics). The introduction of the Vienna System has greatly facilitated comparison between the pottery assemblages of different sites all over Egypt. A guideline for the drawing of pottery, which was established by Aston (1998), is also being used on many contemporary excavations.

During the last decade, the analysis of ancient Egyptian pottery has become a subdiscipline of Egyptian archaeology, not only through the addition of scientific techniques, but also through experimental and ethnoarchaeological research (e.g., the work of Nicholson for the Tell el-Amarna Project, www.amarnaproject.com; or Vereecken for the Dayr al-Barsha Project, www.dayralbarsha.com). This has resulted in the publication of large comprehensive works with not only a detailed typological overview of pottery vessels, but also information on the technological and the socioeconomic aspects, shedding new lights on trade patterns and regional differentiation between the pottery assemblages (e.g., Schiestl and Seiler, 2012; Wodzińska, 2009–2010).

Stone

The exploitation of stone in Egypt goes back to at least 40 000 BP, when pits and trenches were dug for surface exploitation. As early as 35 000 BP, the first vertical shafts and galleries appear at the site of Nazlet Khater, but it is from the Old Kingdom onward that large-scale exploitation took place as the building of numerous royal complexes resulted in an unprecedented demand for stone for architecture, sculpture, and stone vessels. For decades, interest was mainly focused on the large architectural constructions (Clarke and Engelbach, 1930 remained for a long time the reference work on ancient Egyptian architecture), and stone sculptures and vessels were mainly analyzed from an art-historical point of view. The study of stone material and its technology in all its aspects has found a renewed interest during the last decades mainly because of new scientific analytical techniques and experimental archaeology (e.g., Stocks, 2003). This has resulted in the development of many subdisciplines of the analysis of the stone material culture, such as the geological analysis of quarries and their different exploitation techniques (e.g., Klemm and Klemm, 2008), or the typology and mineral composition of stone vessels (e.g., Aston, 1994). The study of quarry marks, and nontextual marks in general including for instance also pot marks, has recently been generating a wide interest and yields important information about the organizational and bureaucratic aspects of quarrying (e.g., Depauw, 2009). A pioneering project is the Giza Plateau Mapping Project under the direction of Mark Lehner, which has mapped out the quarries and exploitation of stone during the building of the pyramids at Giza (www.aeraweb.org/gpmp-project/great-pyramid-quarry). The socioeconomic aspects of quarrying are for instance investigated at Dayr al-Barsha, where research has been conducted on the quarry marks and the road system of the quarries that were exploited to build the nearby city of Tell el-Amarna, the short-lived capital of Egypt during the reign of Akhenaton. The recent discovery of a stoneworking site with hundreds of drills and other stoneworking tools at al-Shaykh Sa'id offers insight in the technology of the production of stone vessels during the New Kingdom (Willems et al., 2009).

Egyptian Faience, Blue Frits, and Glass

Faience is a glazed nonclay ceramic material. Its name has been the subject of confusion as it also refers to a type of pottery now known as majolica, a tin-glazed ware made in Faenza in northern Italy from late medieval times onward. The term faience in Egyptian archaeology is used for objects made entirely from the glazed material, as distinct from glazed stone or glazed ware, which are objects with a coating of glaze. In publications it is also possible to come across the terms 'blue frits' or 'Egyptian blue,' but one should be aware that these terms are not exchangeable with (Egyptian) faience, as has often been done by scholars (see Nicholson and Shaw, 2000). Egyptian blue appears to be an Egyptian invention and is,

although it appears much earlier, closely allied to glass (the earliest glass pieces date back to the Twelfth Dynasty, but only from 1500 BC onward does glass start to appear more commonly in Egypt). Faience on the other hand is a material that occurred widely in the ancient world and can be found in Egypt from the Predynastic period on. Egyptian blue frits are easily distinguishable from faience in a broken section, as the latter always shows a core and a separate glaze layer, contrary to the homogenous section of a frit. Experimental archaeology and archaeometrical research on these different materials open up new insights, such as for instance the work of Nicholson for the Tell el-Amarna Project; www.amarnaproject.com.

Metal

The knowledge of ancient sources of metal ores in Egypt has increased since the 1940s through geological studies on metal ore distribution and geochemistry. The main copper-producing areas were located in the Eastern Desert and the Sinai, but copper workshops have been identified throughout Egypt (e.g., a major copper-alloy working center was discovered at Qantir, ancient Piramesse (Pusch, 1990)). The oldest copper objects were already produced during the Predynastic period (Badarian Period). These were probably produced from native copper, i.e., copper found in nature in metallic form, not as ores. The introduction of smelted copper with, in general, the use of iron oxide as a flux occurred in Egypt around 4000 BC, but more efficient production techniques were not introduced until the New Kingdom. Our understanding of ancient Egyptian metals comes from the careful study of surviving examples using, increasingly, technological advances.

Future Directions in Research in Egyptian Archaeology

The field of Egyptian archaeology has undergone significant changes in the past few decades, mainly under the influence of the input of scientific technology in the field. The interdisciplinary character of excavations is still increasing, and will lead to new research questions to be posed and answered. An area where this will certainly pay off is in the establishment of chronology. A large research project at the Research Laboratory for Archaeology and History of Art, University of Oxford, is working toward linking the traditional historical chronology to dating obtained through the physical sciences (Shortland and Ramsey, 2013). This research unit has carbon (C^{14}) dated a large sample of short-lived plant remains that were well attributable to individual reigns of kings. Good results were obtained mainly for the New Kingdom, and can be incorporated into the revision of the historical chronology carried out by the SCIEM2000 Project (the Synchronization of Civilizations in the Eastern Mediterranean in the second millennium BC, Austrian Academy of Sciences; www.oeaw.ac.at/sciem2000).

A challenge that also awaits Egyptian archaeology is to draw up regional typologies and chronologies of material culture. Regional differentiation often remains either unrecognized or unstudied. This is something that is already well underway in ceramics research, but is to a large extent lacking for other archaeological remains. Material culture did not change at the same time or at the same speed throughout the entire country, and patterns need to be recognized in this evolution.

Abstract

The article covers the development of the Greco-Roman World from Early Greece to Late Antiquity. It focuses on those political and cultural achievements that constituted the legacy of antiquity for European culture: the notion of citizenship and individual rights, the ideas of republicanism and democracy as well as universal emperorship, the continuity of Roman law, and of the Church (including the use of the Latin language).

Antiquity is commonly understood as the history of the Mediterranean world and its neighboring regions before the Middle Ages. The concept is a legacy of the tripartite division of history that has developed since the Renaissance. There was always a tension between mere concentration on Greek and Roman history as representing 'classical' antiquity, and an approach including the high cultures of Egypt and the Near East. On the one hand, the Assyrian and Persian empires were due to the theory of the four world monarchies (adopted from oriental sources in the Book of Daniel), part of a Christian view of history. On the other hand, there was a strong tradition (going back to Aristotle) of contrasting Western freedom with oriental despotism where subjects lived under slavelike conditions. Until the nineteenth century oriental history could only be viewed through classical and biblical sources. Since then, decipherment of hieroglyphs and cuneiform as well as excavations has led to a reconstruction based on monumental sources. Their interpretation, however, required a linguistic and archaeological specialization, which led to a new departmentalization between classical and oriental studies.

Early Greece

Until the late nineteenth century, the beginnings of Greek history were equated with the first literary sources, the Homeric epics (eighth century BC). Since then excavations have enabled detection of the main structures of the Bronze Age civilizations – the 'Minoan' in Crete and the 'Mycenaean' in parts of mainland Greece, where great palaces served as centers of a redistributive economy. Those cultures were finally destroyed during the twelfth century BC by waves of invaders whose identity is far from clear, although they were probably not identical with the Dorian Greeks who afterward settled in parts of mid-Greece, the Peloponnese, and Crete. The structures of the 'Dark Ages' up to the eighth century BC can only be reconstructed conjecturally. There was no need to build up greater units, since there were no attempts by foreign powers to establish control. Social life took place in village communities with some collective organization for warfare and regulation of internal conflicts. The leading part was played by well-to-do landowners, who had to rely on the support of the peasants and permanently competed for a precarious leadership within the community.

The so-called archaic age from *c*.750 BC to *c*.500 BC is the formative period of Greek culture. The adaptation of the Phoenician alphabet was a cultural breakthrough; the epics of Homer and Hesiod (*c*.700 BC) canonized the ensemble of gods and heroes, and Panhellenic festivals such as the Olympic Games presented places of contact for aristocrats from all over the Greek world. Cultural unity was also fostered by the 'colonization', which led to numerous Greek settlements on the coasts of Asia Minor, Sicily, southern Italy, North Africa, and in the Black Sea area; contacts with indigenous populations reinforced the consciousness of an ethnic homogeneity based on language, religion, and customs. Colonization reacted to population growth, aiming at occupation of arable land. Newly created settlements became independent units. Constructing a new community implied a process of rationalization by which the order at home was also understood to be subject to change by deliberative decisions.

The City-State

The city-state (*polis*), first developed in colonization areas, became the typical form of organization in most (yet not all) parts of mainland Greece. It consisted of a fortified center on a hill, a residential town at the foot of a hill, and the agricultural hinterland. Its political unity was symbolized by a meeting place and communal temples. Collective decision making was formalized by the establishment of magistrates with defined competences and terms of office, councils with administrative functions, and assemblies, which took decisions about war and peace, and the administration of justice. For a long time, public functions could only be fulfilled by well-to-do people, but they had to take into account the opinions of the peasants who made up the bulk of the military.

The development toward formalized political structures overlapped with increasing tensions between rising and declining families of the social elite on the one hand, and between the aristocracy and the peasantry on the other. Considerable parts of the peasantry were in danger of indebtedness and finally enslavement. There were demands for cancellation of debts and redistribution of land. In several cities internal tensions led to the seizure of power by a tyrant, an aristocrat who controlled the city through a mixture of military force and patronage. Tyrants improved the condition of the peasantry, developed the infrastructures of the cities, and fostered communal identity by establishing central cults. Only later were tyrants considered to be exercising arbitrary rule

incompatible with the freedom of citizens. In certain cities, 'legislators' were entrusted with the formulation of rules that should stabilize the community.

At the end of the archaic age, a firm political structure was achieved in most cities, with considerable differences as to the degree of participation open to the bulk of the citizenry. Priests were responsible for the administration of cults and temples but did not dispose of political power. There were hundreds of autonomous *poleis*, most of them with a territory of 50–100 km^2 and some hundred or a few thousand (male, adult) citizens. There were, however, some exceptions, in particular Sparta and Athens.

Sparta

Sparta had embarked on an unparalleled expansion. During the second half of the eighth century BC, it conquered Laconia and Messenia, the southern part of the Peloponnese (a territory of *c*.8500 km^2). The subjugated populations were treated as helots, state serfs, or as *perioikoi* ('those who dwell about'), who lived in communities enjoying local autonomy but bound to follow Sparta's military leadership.

Uprisings among the Messenians in the late seventh century BC led to a total reorganization of Spartan society, which was achieved by a series of reforms probably completed about 550. The citizens (Spartiates, *c*.9000) received almost equal plots of land, which were tilled by the helots, whose products enabled the Spartiates to serve as full-time hoplites. Every Spartiate underwent a public education and afterward lived in a warrior community. Society had a uniquely militaristic character, distinguished by an austere lifestyle, which has provoked admiration as well as abhorrence (from antiquity until the present day). The political system was unique again: there was a hereditary kingship in the form of a dual monarchy (of unknown origin), the kings being the leaders of the army; home affairs were administered by five magistrates (*ephors*) appointed every year and a council of men over 60 elected for life (*gerousia*); decisions on foreign policy were taken by the assembly of the Spartiates. In spite of the ostentatious stress on equality within the Spartiates, there was probably an informally ruling elite, although internal politics remain obscure. During the sixth and fifth centuries BC, Sparta enjoyed remarkable stability, and the strength of its army was unequaled in the Greek world.

Athens

Athens was an exceptional case due to the fact that the whole territory of Attica (*c*.2500 km^2) had been formed into one political unit during the Dark Ages. Solon's legislation in 594 BC ensured social peace by establishing that the indigenous population should not be enslaved (which in turn created the demand for chattel slaves from outside), and by codifying large parts of Athenian law. The tyranny of the Peisistratus (561–510 BC) had further unifying effects. In 508/7 BC, Cleisthenes laid the foundations for a political system based on the participation of the citizenry. A reorganization of the subdivisions of the citizenry made newly constituted local communities (demes) the backbone of the system. A council of 500, consisting of members delegated by every deme, took on the preparation of assembly meetings and a number of administrative functions. The council's importance grew, especially when the older council, the Areopagus, consisting of life members, lost political influence in 462/1 BC. During the fifth century BC, appointment by lot was introduced for councilors and the majority of (several hundreds of) magistrates, as well as daily allowances for them and the hundreds of laymen who served as jurors in courts that decided in criminal and civil cases. Every honest citizen (above the age of 30) was considered as being able to undertake public functions, and, due to the great number of positions that had to be filled each year, a great part, if not the majority, of the 30 000–40 000 citizens must have acquired this experience.

All important decisions, especially on foreign affairs, were taken in the assembly, which met regularly. Leadership in the assembly was assumed by generals (strategoi) whose office (a board of 10) constituted an exception, since they were elected (not appointed by lot) and reelection was permitted. But only a few generals acquired a reputation through military achievement and rhetorical ability such that the assembly was likely to follow their lead. The trend toward democracy (a term coined in the late fifth century BC) was not accompanied by disputes of an ideological nature. The central position of the assembly was the result of a dramatic increase in military and diplomatic activities, as tremendous successes in this field fostered the legitimacy of the system.

The Greek World during the Fifth and Fourth Centuries BC

At the Battle of Marathon (490 BC), Athens achieved a sensational victory over Persian troops. In 480 BC, Persia launched an attack to conquer Greece and was beaten off by an alliance of most Greek states, Sparta taking the lead in the land battles, Athens in the maritime operations (with a great victory in the Salamis naval battle). Due to the strength of its fleet, Athens became the leading power in the Aegean Sea and built up a collective military system from which Sparta kept away. To continue fighting Persia an alliance (the Delian League) was established, with a great number of *poleis* financially contributing to the maintenance of the Athenian fleet. Athens enjoyed a period of prosperity and became a cultural center that in the era of Pericles (the leading statesman since the 440s BC) attracted intellectuals, artisans, and craftsmen from all over the Greek world. Athens' political and cultural hegemony materialized in the great temple buildings on the Acropolis and in the great festivals including the theater performances.

Athens' claim for leadership was based on its role in the Persian Wars but operations against Persia ceased after *c*.450 BC. Nevertheless, Athens did not allow any city to drop out of the alliance and showed an increasing tendency to interfere in the affairs of member states. Suspicion of Athenian ambitions to dominate all Greece arose in Sparta and its allies (especially Corinth) with the result that minor conflicts culminated in the 'Peloponnesian War' between Athens and Sparta and their respective allies. Both sides probably considered a final confrontation as inevitable and thought to fight a preventive war. The first period of warfare (431–421 BC) led to a confirmation of the status quo *ante*; the second one opened with

Athens' attack on Sicily (415–413 BC), a disaster for the Athenians, and ended finally in Sparta's total victory (404 BC), which was facilitated by Persian financial aid.

Sparta was not able to keep its hegemonic position for much longer. There were quarrels within the ruling group and, due to military losses and a concentration of landed property, the number of full citizens dwindled continually (down to 2500 Spartiates by 370 BC). Athens partly regained its naval strength, although a new alliance, founded in 377 BC, lasted for only two decades. For a short time, 371–362 BC, Thebes maintained the position of a leading military power. The instability of the power system was increased by Persia paying subsidies to varying allies, which led to a permanent reversal of coalitions. In the midfourth century BC, Macedonia, under King Philip II, entered the scene and tried to acquire a hegemonic position. Athens organized an anti-Macedonian alliance, but this was decisively beaten in 338 BC.

Athenian democracy had survived the defeat in the Peloponnesian War. The terror regime ('Thirty Tyrants') during the final phase of the war had definitively discredited any constitutional alternative. Democracy was restored in 403 BC. Fundamental criticism of political equality as articulated by Plato and Aristotle did not reflect even the opinion of the upper classes. Present scholarship is agreed that there was no decline in political participation. The growing tendency toward a separation of political and military leadership had certain negative effects on military efficiency, but the final defeat by Macedonia was due to the lack of sufficient resources. That Athens (and the other Greeks) should better have accepted a 'national' unity under Macedonian leadership (as was often said in nineteenth-century historiography) is an anachronistic idea, incompatible with the tradition of the autonomous city-state.

The Hellenistic Age

Macedonia did not formally abolish the autonomy of the *poleis*, but they were put under firm control and lost their capacity to pursue an independent foreign policy. Macedonia wanted to legitimize its leadership by embarking on retaliation against Persia. Philip's plan was realized by his successor Alexander ('the Great'). Heading an army of Macedonian and Greek troops, Alexander conquered Asia Minor, Syria, Egypt, Mesopotamia, and Iran with incredible speed (334–330 BC). Having declared the Panhellenic revenge war terminated, he dismissed the Greek contingents and started conquering the eastern parts of the Persian Empire with Macedonian and Iranian troops. In 326 BC, he reached the Indus Valley, but his intention to march to the 'edges of the world' failed as his exhausted troops refused. In his lifetime Alexander won a reputation for invincibility; his death in 323 BC, at the age of 33, made him a figure that was reflected upon by philosophers, historians, and rhetoricians. He became the prototype of a world conqueror later rulers would imitate, and a subject of popular romances, which would receive adaptations in the major languages of the Middle Ages. Modern historians often cannot resist following their own imaginations with respect to Alexander's 'final plans'.

Alexander took over the provincial system of the Persian Empire and considered himself a successor to the Persian Great King and the Pharaoh. His adoption of Persian court ceremonial and attempts to integrate Iranians into his elite units provoked alienation with his Macedonian troops. At the time of Alexander's death there was no successor. Control was taken over by several generals, who acted as governors in various parts of the empire. In a series of wars between them the unity of the empire was broken. Finally, around 280 BC, a new power structure consisting of Macedonia, Egypt under the Ptolemies, and Asia Minor, Syria, Mesopotamia, and parts of Iran under the Seleucids was established. Macedonian generals had succeeded in founding dynasties. In the Ptolemaic and Seleucid kingdoms leading positions in the army and bureaucracy were occupied by Macedonians and Greeks; Alexander's attempts to include native elites were not repeated. Greek-Macedonian and native populations lived under different legal orders. The system was kept together by the king, who was considered absolute ruler and overlord of the territory.

In spite of these limits of integration, there was a tendency toward assimilation of Greco-Macedonian and indigenous cultures, the spread of Greek as an international language, and the spread of the Greek lifestyle to cities and garrisons with Greek populations. Mercenaries, tradesmen, intellectuals, and artists enjoyed mobility throughout the Mediterranean and Near Eastern world. Alexandria in Egypt became a cultural center where the literary heritage of the fifth and fourth centuries BC was cultivated. These achievements of the 'Hellenistic age' (a nineteenth-century coinage) were still persisting when the Romans established their domination over the eastern parts of the Mediterranean world.

Early Rome and the Middle Republic

According to late Republican Roman tradition, the city of Rome was founded in 753 BC. Archaeological evidence suggests that settlements on the hills of the future city were established from the tenth to the eighth centuries BC. Formation of a city-state took place considerably later, and was due to strong Etruscan influences, although Rome was never dependant on an Etruscan city. The primordial kingdom, ever in need of cooperation with a landowner patriciate, was finally abolished around 500 BC. After that Rome was dominated by an aristocracy, which, however, changed its character. There were tensions between the patriciate and rising families, as well as peasant demands for land distributions and debt relief. The plebeians, i.e., all nonpatricians irrespective of their social status, combined in a separate organization with magistracy (tribunes of the people) and assembly to achieve access to political functions hitherto monopolized by the patriciate, and to secure the fulfillment of social demands. The 'Struggle of the Orders' is a somewhat dramatic term for a long process in which phases of conflict and reconciliation alternated. Piecemeal changes from the fifth to the early third centuries BC led to a political system with an equilibrium between magistrates, senate (a council of former magistrates sitting for life), and assemblies, which decided on war and peace, legislation, and the election of magistrates. Politics was determined by a nobility formed of the old patriciate and the plebeian elite who now had access to the magistracy. Office tenure for 1 year, collegiality in all magistracies, a hierarchy of magistracies to be

occupied in successive order, and the senate's overall control ensured a certain equality within the ruling class. Ordinary citizens participated through the assemblies. Voting, however, took place in units structured according to wealth and place of residence, which implied a blatant weight in favor of the propertied classes; initiative for legislation was the monopoly of magistrates. Roman assemblies were far from being democratic in the Greek sense. But their very existence and their function as a forum for communicating with the people ensured consensus within the citizenry. The nobility presented itself as a ruling class not indulging in conspicuous consumption, but absorbed by their duties in public office.

Constitutional development and territorial expansion mutually enforced each other; the peasantry serving in the army put pressure on the nobility, who in turn would fulfill their demands by land distributions in newly acquired territories. During the fourth and early third centuries BC, Rome won control first over the neighboring region of Latium, then over mid- and south Italy. This tremendous success was not only due to the strength of a highly disciplined military but also the result of a prudent policy of integration. Whole communities were admitted to Roman citizenship (with or without the right to vote); others gained a special status by which their members could opt for Roman citizenship. All others were treated as allies enjoying autonomy, their obligation to military support being rewarded by a share in the profits of war. Thus Rome could rely on indirect domination based on the cooperation of local elites.

Roman involvement in Southern Italy led to confrontation with the Carthaginians who occupied parts of Sicily. As a result of the First Punic War (264–241 BC) Rome established domination over Sicily, Sardinia, and Corsica. The second war with Carthage (218–201 BC) opened with catastrophic Roman defeats against Hannibal, who had invaded Italy from Spain. But finally the Romans were able to make Hannibal retreat to North Africa, where he was decisively beaten. In the end, Rome extended its domination over Spain. During the second century BC, Rome established its hegemony in wider parts of the Mediterranean area. The Macedonian state was destroyed in 168 BC, Carthage in 146 BC. The Seleucid position in Asia Minor was undermined in favor of the rise of Pergamum, which in 133 BC would fall to Rome.

Beginning with Sicily, newly acquired overseas territories were made provinces under permanent administration by Roman magistrates and 'promagistrates' (whose authority was prolonged for that purpose after the regular 1-year term). Governors relied on the cooperation of local elites and, as a rule, did not change internal administration structures, especially the systems of tax collection. There were, however, always complaints about exploitation by governors who impudently enriched themselves.

Rome's overseas expansion did not follow a blueprint, and actual decisions were not taken primarily with respect to the acquisition of resources. But a tendency toward 'imperialism' was inherent in a system in which magistrates had just a short period to gain prestige and wealth, and soldiers were accustomed to participate in booty. The more conquest, the more chances to 'defend' Roman interests; Rome's determination to impose its will upon other states was compatible with its self-representation as fighting only 'just wars'.

The Late Republic

The establishment of a large empire had unforeseen repercussions at home. Part of the vast resources available because of the conquests were invested in Italian land. Aristocrats acquired great landed estates, which were worked by slaves for the production of cash crops. Peasants were displaced and no longer met the property qualification for army service. This picture, going back to ancient narrative sources, represents a general trend, although it certainly needs qualification to take account of regional differences. The land reforms by Tiberius and Gaius Gracchus (133 BC and 123/2 BC, respectively) had only limited effects. Later the recruitment system was changed: volunteers without property qualification were enrolled; these soldiers showed special loyalty to their commanders, who in turn felt obliged to secure landed property for veterans. Sulla, who came to power (82 BC) after a series of civil wars (starting with the Italian allies' forcing their access to Roman citizenship) and the war with Mithridates of Pontus (who had attacked the Romans in Asia Minor and Greece), was the first to satisfy the soldiers' demands by large-scale confiscations in Italy. Sulla's attempt as *dictator* (traditionally only a short-time supreme commander) to strengthen the senate's authority was not really successful. It became necessary to entrust the great general Pompey with long-term command, but after his complete reorganization of Roman domination in Asia Minor and Syria (66–62 BC), Pompey could not arrange for the land allotments he had promised his soldiers. He engaged in a coalition with the ambitious Caesar, who used his provincial command in Gallia for a large-scale conquering campaign (58–51 BC). At last Pompey realigned with the senate to crush Caesar. Caesar won the ensuing 'civil war', which was fought all over the Roman Empire (49–45 BC). Being in sole power, Caesar was finally appointed dictator for life and the senate indulged in conferring extreme honors upon him.

Caesar's ostentatious disgust with aristocratic equality caused his murder by a group of senators (44 BC). His supposed 'final plans' have bedeviled generations of historians, but it seems doubtful whether he had had a clear-cut conception of a lasting reorganization of the political system. That a monarchical head of the empire was a historical necessity (as nineteenth-century scholarship put it in Hegelian terms) was an idea apparently not familiar to contemporaries, since military success over centuries had been achieved by an aristocracy. But the traditional republic could not be restored either, and after a further series of civil wars a new system emerged.

The Early Empire

The new order was established by Octavian, Caesar's personal heir, on whom the senate conferred the title 'Augustus' in 27 BC. Through cautious moves he constituted a monarchy in disguise, proclaimed as a 'restoration of the republic'. The emperor's formal authority consisted of a bundle of competencies derived from traditional magistracies, which allowed him to control all affairs. Continuance of magistracies and senate, and employment of senators as military commanders and governors ensured the loyalty of the senatorial elite, although the subsenatorial 'equestrian order' got a share in

administration. The emperor played the part of the patron to the capital's population by grain and cash distributions as well as public games. The problem of veteran settlement was solved by the purchase of land in Italy and overseas colonization. Provincial governors still relied on the cooperation of local elites, who were rewarded with legal privileges and offered chances for ascendance into the equestrian and senatorial ranks.

Such a summary of the 'principate' inaugurated by Augustus should not result in ignoring internal tensions. Keeping a republican facade demanded the self-restraints of rulers, but the lack of constitutional controls and, for example, the tendency of Eastern provinces to confer godlike honors on them made emperors show their true faces as autocratic rulers again and again. Provincial government was improved, but charges of corruption and maladministration against governors did not cease (and led to a great uprising in case of the Jews in AD 66–70). The absence of a law of succession reflected the tension between meritocratic and dynastic elements within the emperorship. Designation of a successor was not necessarily decisive – at the crucial moment, the senate, the imperial elite troops (praetorians), even the capital's population might be influential, or a provincial army might promote a pretender.

All in all, during the first and second centuries AD the empire enjoyed stability and prosperity, which was manifest in the sophistication of urban culture in all parts of the Roman world. Expansionist policy was given up in favor of territorial consolidation (although Britain was subjected to Roman rule throughout the first century AD). The majority of troops were stationed in fortified positions near the frontiers, especially the Rhine-Danube and Euphrates borders. During the third century AD, Rome came under increasing pressure by the Goths (who were invading the Danube area) and the new Sassanid dynasty in Persia. The situation was aggravated by instability on the throne: again and again army units proclaimed officers as emperors; most of them met violent deaths after a short time.

The Later Empire

After half a century of turmoil, Diocletian (AD 284–305) embarked on a comprehensive reform. It was based on devolving the imperial office on two senior and two junior emperors (as prospective successors), who would each have authority in a part of the empire but would govern jointly. The emperorship was symbolically enhanced by attributing a 'sacral' character to it and adopting oriental court ceremonial. However, regulated succession failed; from AD 305 onward various pretenders fought each other, until Constantine and Licinius could consolidate their positions in the West and East, respectively. Finally Constantine became sole ruler (AD 324).

The administrative reforms started by Diocletian were continued by Constantine. They included a reorganization of the army (now divided into field army and border troops) and of the provincial system (now including Italy), a separation of military and civil administration, and a new taxation system to meet the demands of the army and the enlarged governmental apparatus. These led to considerable consolidation although the intention to regulate more and more features of social life was partly defeated by corruption and maladministration, as well as the attempts of various social groups to escape the pressure put on them from above – local grandees sheltered their dependants from the state's demands and exploited them at the same time. Citizenship (since AD 212 extended to all inhabitants of the empire) lost its importance, as can be seen in the harsh penal system with distinctions according to the social status of citizens. Peasants, who had to take the burden of taxation, were reduced to a serflike status; craftsmen were bound to their occupation and place of residence. These points signify tendencies; they should, however, not be understood as covering the multifariousness of social reality. There were considerable differences between the various regions of the empire, and discrepancies between the increasing legislation and its enforcement. The political and societal order of the post-Diocletian era had manifestly changed in comparison with the early empire, but there were also remarkable elements of continuity, for example, with respect to higher education, local administration, and civil law. The traditional label of 'despotism' is not helpful.

A most important change happened with respect to the Christians. From the first century AD onward, Christianity had spread through all parts of the empire, and had taken on firm organization with the episcopal constitution. Christians who did not participate in the ruler cult were considered disloyal citizens. During the first two centuries AD, there were sporadic persecutions of Christians, mostly inspired by local communities. The Christians reacted, on the one hand, by praising martyrdom; on the other, by stressing the coincidence of Christ's coming and the Augustan reign of peace and (answering the charge of being a lower-class religion) by adopting 'pagan' literary culture. Since the midthird century AD, rulers had considered the restoration of state cults necessary for the preservation of the empire. That led to systematic persecutions under the reigns of Decius (AD 250), Valerian (AD 257), and Diocletian (AD 303); indictments of clerics, prohibition of church meetings, confiscation of holy scripts and church property were aimed at destroying the church's very existence. As a whole the measures failed and were stopped in AD 311. After AD 312, Constantine pursued a policy not only of toleration but also of actively promoting the church by donations, granting privileges to clerics, conceding a public role to bishops, promoting Christians in public offices, and finally giving the new capital Constantinople, founded at the site of Byzantium (AD 324), a Christian outlook. Constantine's religiosity and the motives of his policy remain obscure. The strengthening of imperial authority by a theology that declared the emperor God's vicar on earth had to be paid for with involvement in inner-church conflicts, especially the Arian schism, which was not to be solved by the theological compromise found at the Council of Nicaea (AD 325) under Constantine's personal lead. Finally, Theodosius declared Christianity the state religion (AD 380) and pagans, heretics, and Jews became subject to persecution. Bishops played an important role as the heads of cities, and some, especially in the West, in imperial politics as well. The increasing interweaving of state and church, however, fostered ascetic monasticism.

The division of the empire into Western and Eastern parts after the death of Theodosius (AD 395) would last, although the fiction of unity was never given up. For a number of reasons, the Eastern Empire did far better with the pressures from

migrating Germanic tribes, especially the Goths. The weakness of the Western Empire is symbolized by the Visigoths' sack of Rome (AD 410). The end of Western emperorship in AD 476 is traditionally taken as signifying the end of Antiquity. Whereas in the West, Germanic states were established, the East took up the Roman heritage (as symbolized by Justinian's codification of Roman Law, AD 534) and preserved its continuity through the Middle Ages.

The Legacy of Antiquity

In spite of manifold contacts with the oriental world, the political and cultural achievements of Greece and Rome were products of indigenous development. The notions of citizenship and individual rights, the ideas of republicanism and democracy, as well as universal emperorship, the continuity of Roman law and of the church (including the use of the Latin language), Christian preservation of 'pagan' literature and other traditions became formative for European culture through structural continuities and conscious renaissance. In this sense, it is still appropriate to treat Greco-Roman antiquity as a historical epoch of its own.

Animal Rights in Research and Research Application

Lesley J Rogers, School of Science and Technology, University of New England, Armidale, NSW, Australia

Abstract

The concept of animal rights is discussed and distinguished from animal welfare. A brief history of attitudes to animal sentience and welfare is followed by contemporary activity in protecting animals used in research. Differences between countries in the legal protection of animals used in research in the Western world are covered, as are the movements active in campaigning for animal rights and/or welfare. Finally, debates about which species are covered by legal protection in research are discussed, drawing attention to the current inconsistencies regarding which invertebrates should be included in ethical guidelines for research and which need not be so protected.

The Concept of Animal Rights

Animal Rights has two different meanings. One meaning refers to specific law-based protections of nonhuman animals and hence to animal rights activity in formulating fundamental legal protections of animals, as well as monitoring adherence to these clear legal requirements. The other meaning refers more generally, or some say more vaguely, to the moral rights of animals, and advocates of this position argue for moral protections of nonhuman animals along the same lines as the rights of humans (i.e., the rights to life, liberty, and freedom from torture), but not necessarily treating animals and humans in the same way for all purposes (see Francione, 2000; Armstrong and Botzler, 2003). In essence, extending rights to animals means that animals have an inherent right to live according to their species characteristics/requirements, free from harm, abuse, and exploitation. In other words, nonhuman animals (hereafter referred to simply as animals) have value in their own right completely separate from their usefulness to humans.

Some organizations concerned with animal welfare and rights adopt variations of these polarities, depending on their specific views and the state of play considered possible in improving the treatment of animals. There are a number of ongoing debates on animal rights (see articles in Sunstein and Nussbaum, 2004), many stemming from difficulties arising where biological knowledge meets the law.

Animal Rights versus Animal Welfare

There is a fundamental difference between the animal rights and animal welfare positions. As Francione and Garner point out in their book *The Animal Rights Debate: Abolition or Regulation?* published in 2010, the welfare approach is utilitarian and regulationist. Within this framework, animals are considered to be of lesser moral worth than humans and hence it is acceptable to use them for human purposes as long as they are treated 'humanely.' To those who favor the welfare position, the moral issue is *how* we use animals, not *whether* we use them. Also, advocates of this position argue that death in itself is not harmful to animals. Although regulations must be in place to ensure that death of animals killed for research, to eat, or for other reasons is not painful, death itself is not considered to be a particular issue. This means that, according to this position, animals can be used in experimental research and in testing pharmacological and pharmaceutical substances, provided the benefits of the research outweigh the costs in terms of animal suffering. Here one notes that the benefits are mostly for humans, whereas the suffering is of animals.

On the other hand, the position of animal rights considers death in itself as being 'a harm' for all sentient animals since they must be aware of life versus death. This raises a question about which species are sentient and, therefore, can we draw a line separating those to whom rights are extended from those not worth such privileges, or is all life sentient to varying extents? The animal rights position is, in its purest form, abolitionist and considers that animals should not, under any circumstances, be exploited by humans. This includes animals used in research, issues of farming animals for food, using animals for sport and other forms of human entertainment, keeping animals as companions, and killing animals considered to be pests. Different groups or organizations tend to give emphasis to one or two of these areas. However, to quote Andrew Knight, author of *The Costs and Benefits of Animal Experiments* 2011, "Animal experimentation is arguably the single most contentious issue in the wider debate concerning the rights of humans to use animals."

History

Animal welfare and animal rights ideas developed in the Western world against anthropocentric ideas and ethics. The superiority of humans and their right to use animals to their own advantage was part of the Christian tradition from its inception (humans alone being created in the image of God) (see Scully, 2002; article number 5 in Singer, 2006). There are other cultures and religions that believe in the sanctity and equality of all life (e.g., Hinduism and Buddhism) and hence exercise animal rights to various degrees, the strictest interpretation being that of the Jains in India, who wear a cloth over the mouth to prevent death of small organisms by inhalation.

In the Western world, the ideas of the French philosopher René Descartes (1596–1650) dominated and animals were seen as mechanical automatons unable to experience pain or any other feeling. Descartes and his followers reasoned that the

cries of animals subjected to vivisection, at that time without analgesics or anesthesia, were merely the creaking and groaning of the mechanical system, as in the spring-driven clockwork devices made by humans, and so could be ignored. This perception of animals put an end to any positions that had until then considered animal welfare and it opened the door to all manner of experimentation that we now see as brutality. Descartes' philosophy is said by some to have sparked modern anthropocentrism.

Attitudes to animals changed during the Enlightenment. By 1800, animals had become to represent new standards of truth and morals (Senior, 2008). Humans admired animals and through them sought to regain their own animality. Contemporary understanding of 'rights' stems from this period, be the term applied to human rights, the rights of slaves and prisoners, or the rights of animals.

Then came the theories of Charles Darwin (1809–82) on evolution and the continuity between animals and humans in both structure and mental function (*Origin of the Species*, 1859, and *The Descent of Man*, 1871). Publication of these ideas was met with heated debate since they blurred the line between humans and animals, particularly between humans and primates, and pockets of that debate persist even today: Darwin's theory of evolution is still opposed by the Creationist Movement. Darwin's theory of evolution made a revolutionary change to the study of animals. For the first time, it made clear that research on animals was relevant to understanding humans. At the same time, it suggested that animals share emotions with humans, to varying degrees (see *The Expression of Emotions in Man and Animals*, 1872). This meant that the difference between humans and animals was a matter of degree, not of kind. Hence, animals were considered to experience pain and a range of other emotions including fear, pleasure, and misery, as well as higher cognitive abilities (memory, problem-solving, tool using) and the rudiments of mind.

Contemporary Activity in Protecting Animals in Research

Policy on the use of animals in research has changed substantially in recent years, particularly where nonhuman apes are involved. The Great Ape Project was founded in 1993 as an international organization of primatologists and researchers in related fields to campaign for extension of basic legal rights to the great apes. The book *The Great Ape Project* edited by Cavalieri and Singer argued that great apes share many cognitive abilities with humans (e.g., self-awareness, rationality) and so should be given rights.

In 1999, the New Zealand government passed an Animal Welfare Act banning experimental research on nonhuman hominids. The Austrian Parliament, in 2005, banned experimental procedures on apes unless they were in the interests of the individual ape. Beginning in 2008 in Austria, there has been a law suit fighting to get a chimpanzee called Matthew Hiasl Pan declared 'a person' and so achieve for him the same rights as humans, including a pension (see Knight, 2011). This case was rejected recently, but it continues now as an appeal to the European Court of Human Rights.

In the United States, following a public controversy and a congressional request made in 2010, the U.S. National Institutes of Health (NIH) commissioned formation of an 'Institute of Medicine Committee on the Use of Chimpanzees in Biomedical and Behavioral Research.' This committee reported in 2011 that chimpanzees are largely unnecessary for biomedical research and it recommended guidelines for any research using chimpanzees. In 2013, the NIH adopted most of the recommendations and announced that it would release most of the federally owned or sponsored chimpanzees to sanctuaries in the United States. Some 110 chimpanzees will be retired from research, with a projected 5-year time-frame for transferring them to life in more natural conditions than in the laboratory. Fifty chimpanzees will be retained in the NIH laboratories for potential future use in research.

Protection of animals used in research has increasingly become policy in several countries. In 1997–98, laws of the European Union referred to animals as sentient beings, and in 2002, the German constitution was amended to protect animals at the most fundamental level.

These changes were stimulated by changing public attitudes and by activities of a range of organizations with an interest in curtailing research using animals (see below). They want it either abolished or continued under strictly enforced guidelines. In response to early activity by animal rights advocates and changing public opinions, universities in the UK and Australia, for example, formed 'Animal Ethics' committees that assess all research proposals and issue licenses on individual basis. In the United States, 'Americans for Medical Progress Educational Foundation' was founded in 1991, in order to increase the public's understanding of humane use of animals in research. Scientists are now more open about their research procedures and results and tend to engage more actively with animal welfare and, in some cases, with animal rights groups. Both sides of the debate seem to see importance in education of the public about research in the life sciences and its costs and benefits.

In many countries, attitudes of the public to the use of animals in research have shifted quite markedly in recent years: for example, a 2013 survey in the United States of 1000 people found that 41% considered medical testing on animals as morally wrong, this being an increase of 12% since 2001 (results presented at the American Association for the Advancement of Science, February, 2014, listed below).

Along with these developments, we have seen the inclusion of courses in Animal Law in the United States (Harvard University course commenced in 2000), the UK, Australia, and Spain (e.g., Masters in Animal Law and Society at Universidad Autonoma de Barcelona), and the appearance of new journals and academic societies focused on animal ethics (e.g., the Animals and Society Institute in the United States, which is an independent research and educational institution promoting knowledge in human–animal studies and action to protect animals through adoption of ethical, compassionate public policy). New peer-reviewed journals reporting research and ideas in this field have also been launched (e.g., *Animal Law*, *Sloth*, *Animals and Society* and the *Journal for Critical Animal Studies*). Special issues of other specialist journals are now being devoted to articles discussing the ethics of research on animals (e.g., *Theoretical Medicine and Bioethics*, vol. 35 (2),

published in 2014) and a new focus of enquiry on how we treat animals has emerged in departments of sociology, psychology, and even gender studies (see Taylor and Twine, 2014).

Conferences devoted entirely to animal welfare and rights are now held regularly (e.g., Minding Animals International Inc. has held triannual conferences since 2009).

Guidelines for the Use of Animals in Research

A guiding principle of research using animals is that of the three Rs: meaning to *reduce* the number of animals used in research and still achieve meaningful results, where possible to *replace* use of animals by other techniques (e.g., tissue culture), and to *refine* the methods used in order to minimize pain and suffering. Knight (2011) argues in favor of adding two more Rs: viz., reuse (recycling of research animals) and rehabilitation.

Guidelines for committees formed to assess research in universities and other research institutions vary between countries and even between states in some countries (e.g., Australia).

In most places, there are regular steps taken to upgrade guidelines and legal requirements. For example, in New South Wales, Australia, the 'Animal Research Review Panel,' formed in 1986, is the overarching organization monitoring research on animals and issues accreditation to universities and related organizations. It also acts to review guidelines for housing and conducting research on different species, taking into account relevant knowledge and research on the various species. The National Health and Medical Research Council in Australia issues guidelines that include all nonhuman vertebrates and, as added in 2004, invertebrate cephalopods, such as octopus and squid. In 2010, the European Union passed a directive requiring member states to follow certain guidelines when conducting research and including cephalopods but, contrary to scientific advice, excluding other invertebrates including decapod crustaceans (lobsters, crabs, etc.), spiders, and social insects (*Official Journal of the European Union*, 22 September 2010). The latter species were not included despite sufficient evidence indicating that they can feel pain and experience suffering, distress, and lasting harm. These abilities to feel pain and suffer are considered probable, since it has been demonstrated that these invertebrate species are capable of performing tasks that require complex cognition. This raises the difficult issue of exactly what species are to be included in guidelines and legislation and what are not, as discussed further below.

Animal Rights Movements

Organizations concerned with animal welfare and animal rights currently extend their attention and activities more broadly than to the field of research, although use and abuse of animals in research is also part of their platform. Not all of them can be listed here, but the following are pertinent examples.

Animal Liberation formed in Australia in the late 1970s not only with an emphasis on animals used in factory farming, but also with an interest in animal rights in research. Its activities were an extension of the book *Animal Liberation* by the Australian philosopher Peter Singer, first published in 1975. Then and now, the goal of Animal Liberation is to "end suffering of exploited and confined animals, through legislation, consumer advocacy, action, and humane education." Members of Animal Liberation believe that animals have a right to live free from human intervention, use, and abuse. Incidentally, while Singer's publications, especially his book *Animal Liberation*, have reached a wide audience and led to much activity for animal rights, his arguments have drawn criticism from many of his academic peers on the grounds of rather poor academic quality and, by featuring sentience as the sole criterion of the need for protection of rights, allowing argument for sacrifice or use in research of humans lacking sentience (e.g., anencephalic neonates or comatose patients).

Animal Liberation Front (ALF) is radically abolitionist with a manifesto of total liberation of animals by any means necessary, which can include violence such as arson of animal laboratories and even kidnapping, as it did so in 1999. Then the journalist Graham Hall, who had made an undercover documentary of the violent methods of ALF, was kidnapped.

People for the Ethical Treatment of Animals (PETA), formed in 1980 in the United States, arose out of the Silver Spring monkey case, Maryland, USA. This case began in 1981 with an undercover investigation of monkeys used in research at the Institute of Behavioral Research. PETA's documentation of the cruelty to which these primates were being subjected led to the first criminal conviction of an animal researcher and the first confiscation of animals from a laboratory. It also led to additions to the Animal Welfare Act in the United States. PETA is now is a very large and active organization for animal rights that focuses on four areas in which it considers the largest numbers of animals suffer most intensely for the longest periods of time: in factory farms, in the clothing trade, in laboratories, and in the entertainment industry. PETA keeps to nonviolent methods to achieve its goals although these methods may not always be legal. PETA now has international affiliates in the UK, France, Germany, the Netherlands, India, Australia, and Asia.

Voiceless in Australia focuses its finances and activities on factory farming and the kangaroo industry. This organization funds a prize for research aimed at replacing animals in research.

Animals Australia campaigns against the live export of cattle, factory farming, 'puppy factories,' and, of relevance here, its overall policy is against the use of animals in experimentation, especially in the pharmaceutical industry and in teaching.

Mercy for Animals is an animal rights organization in the United States, founded in 1999, focused on preventing cruelty to farm animals and promoting diet that does not include animals. The use of animals in research is not part of their current activities. They conduct undercover investigations primarily of battery farm practices and have had successes in improving conditions in some cases.

One of the more recent developments is the establishment of a National Museum of Animals and Society in Los Angeles, USA, chiefly exploring the bond between humans and animals and educating the public on the cognitive and emotional abilities of animals (e.g., cognition of domestic chickens). It aims to be a repository of materials and writings from both the welfare- and right-based movements.

What Animals Are Included?

There is no consensus on which species of nonhuman animals should be covered by welfare guidelines and legislation, or should be included in the fight for animal rights (see Wise, 2002). Inclusion of species depends ultimately on which ones can experience pain, but this is not the only criterion. Intelligence, consciousness, and self-awareness are also used or implied as characteristics of species deserving rights and protections. The expansion of interest in methods of assessing cognitive function in animals has thrown these latter qualities into the limelight. Avant-guard research in the perceptual and cognitive abilities of different species has been important in drawing attention to which species should be afforded protection and rights and, as mentioned above, it has brought about changes, such as the inclusion of cephalopods under guidelines or legislation previously limited to vertebrate species. However, since research on these aspects of animal behavior is in its relative infancy, some of the changes made are piecemeal and biased toward the few species that have been tested for their cognitive ability. As explained in some detail by Rogers and Kaplan (2006), a number of behavioral attributes have been assessed in some species, including the abilities of following the direction of another's eye gaze, communicating intentionally, thinking of objects that have disappeared from sight, making and using tools, caching food and remembering from where to retrieve it later, theory of mind, and the concept of self, to list just some of the main indicators of higher cognitive ability (for examples of research on cognition in animals, see Wasserman and Zentall, 2006; Rogers and Kaplan, 2004).

Species that have not yet been tested and shown to have any of these cognitive abilities may be allowed protection if other closely related species have shown these exceptional abilities (e.g., all cephalopods although only one or two species of octopus or squid have been tested). Others may miss out simply because they have not been tested or have 'failed' the tests for reasons to do with experimental design or the particular subjects selected for testing. In other words, the process can be flawed and the outcomes problematic: indeed, inclusion of some species and not others may worsen the treatment of those not included.

Very few would disagree with the fact that a boundary has to be drawn, but there is much debate about where. Some would extend rights only to apes, others to all primates, yet others to all mammals; but, recent research on higher cognition in birds (see Kaplan, 2014) demonstrates that some avian species have cognitive abilities equivalent to those of primates, even apes. Furthermore, recent research on bees shows that they have more complex cognitive abilities than previously considered possible. In summary, research on the cognitive abilities in animals is an active focus of interest and it is leading to revolutionary changes in our understanding of and attitudes to animals.

Currently, however, apart from the recent inclusions of cephalopods discussed above, no ethical guidelines for research on animals include invertebrates and no case is being made to extend rights to other invertebrates. Moreover, vertebrate species that are covered by laws or guidelines concerning research on animals varies from country to country. In the United States, the Animal Welfare Act (as of November 2013: see Animal Care Blue Book and Animal Welfare Information Center Web site) defines 'animal' as any live or dead dog, cat, monkey, guinea pig, hamster, or rabbit but excludes birds, rats of the genus *Rattus*, and mice of the genus *Mus* bred for use in research. In the UK, Germany, and Australia, at least, all of the latter species are covered by the legislation on the use of animals in research.

The Federation of European Laboratory Animal Science Associations represents views of the laboratory animal science community in Europe and issues guidelines that are not mandatory but aimed at keeping up with changes based on knowledge and community views.

There is a general perception that laws and guidelines relating to the use of animals in research need continual revision and modification to encompass new scientific information about the ability of different species not only to perceive pain, but also to suffer stress and distress. The gray area where we should draw the line between those species deserving protection and those not requiring it is broadening and will continue to do so as research provides broader and more reliable evidence of cognition and species differences (see Rogers and Kaplan, 2006). In future, it may well be recognized that not all species should be afforded the same rights but instead that species-relevant legislation should be applied.

Annales School

Abstract

The Annales group of historians, including the founders of the journal Lucien Febvre and Marc Bloch, were responsible for a historiographical revolution, which challenged and then transformed historical writing in France and, from the 1970s onwards, had an international impact. The germ of the Annales challenge to established historiography in France grew out of a commitment by the founders to a widening of the field of historical research and an engagement with the human sciences. Over three generations between the 1960s and the end of the century, Annales moved through a number of clearly definable phases during which it continued to foster methodological innovation and multidisciplinary engagement, while remaining committed to a rigorous historical approach to evidence.

I

The historiographical revolution that took place in France between the 1930s and the 1960s is indelibly associated with the journal *Annales d'histoire économique et sociale*, founded in Strasbourg in 1929 by Marc Bloch and Lucien Febvre. The journal quickly moved its base to Paris and continued publication until 1939. During the war and the occupation of France, it appeared as *Annales d'histoire sociale* and *Mélanges d'histoire sociale*. It was effectively refounded in 1944 as *Annales: histoires, sociétés, civilizations* and, since 1994 has been titled *Annales: histoire, sciences sociales*. Throughout this period, the journal has been the center of a movement in historical writing, which sought to transform history by opening it up to the concepts and developments in other branches of the human sciences, including geography, sociology, and anthropology. At the core of the wide variety of practices and approaches associated with the Annales school was a view of history, which sought the widest possible perspective on historical change. This necessitated a broad understanding of the complex range of factors, which contribute to historical change including psychological, cultural, economic, and environmental factors. The question of human agency is central to this concern, but in the Annales tradition, human agency could only be understood by studying the collective elements in human consciousness and activity, against which any analysis of individual action needed to be set. A corollary of this was a broadening of the chronological and methodological approach to historical research. To some extent, this involved the expansion of the subject matter of historical enquiry and a new approach to the subject matter of historical research. A historical practice primarily concerned with the study of power and power elites gave way to a new emphasis on hitherto neglected areas of historical human experience, where the newer developments in other areas of the human sciences in the early twentieth century seemed to offer far more interesting and incisive perspectives. Thus, a reformulation of the domain of historical research and a new emphasis on research as collective as well as an individual procedure, focused on clearly identified problems and themes, was a central part of the methodology of the school. But as well as opening the field up to engagement with a variety of new approaches, the *Annales* also brought about an important change in the way in which historians conceived of historical time and periodization. Again, the reevaluation of the role of human agency was central here, particularly given the way in which the successive generations associated with the journal expanded the chronological limits of historical study to evaluate phenomena and processes from the perspective of longer-term changes, which transcended individual consciousness or agency. In seeking to understand deep-seated processes behind historical change, the *Annales* historians were interested in identifying underlying structures, which shaped profound change in human societies in ways that were invisible to individual human agents or to contemporary historical actors. This concern with deep structures was partly shaped by the engagement with economic history and the long-term cycles identifiable from the serial study of economic data such as prices. The result of these latter developments brought quantitative methods to the center of the *Annales* in the middle decades of the twentieth century, identifiable with the leadership of Ernest Labrousse and Fernand Braudel. The emphasis on quantitative methods, serial history, and the study of deep underlying structures of change and immobility over long periods of time represented an evolution from the concerns of Febvre and Bloch in the first generation, and also coincided with the dominance of the school in the French historical establishment. The dominance of economic and statistical approaches, over the psychological and cultural elements of the initial program, revealed an implicit tension between different views of what was primary and secondary in terms of historical causation and social history. The study of mentality, conceived in the widest sense as a history of collective representations and of the evolution of individual consciousness in a social and historical context, had been present from the beginning as a core part of the *Annales* program, however overshadowed by quantitative history. From the 1960s, however the inclusiveness of the totalizing approach, characteristic of the school's founders, and of its ambitions in the postwar era, was clearly still producing a constructive engagement between the study of physical and environmental structures and the analysis of cultural forms and collective mentalities. A variety of regional studies, most famously Le Roy Ladurie's on Languedoc, bore witness to a further shift in the development of the school. To some extent, this reflected the long-standing commitment to the project of a 'total history,' in which even the most austere

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61146-7

structural and quantitative methodologies were approached in the belief that these were ultimately a basis for the understanding of the whole of human experience, including mental and cultural experiences and structures, rather than a form of determinism. Thus, history could be conceived as manifesting itself at a variety of levels, 'from the cellar to the attic,' i.e., from fundamental environmental, and economic constraints to the quintessentially human forms of mental and social organization and, ultimately collective and individual human experience. Of course this extension involved a substantial degree of refinement of the conceptual apparatus for analyzing and describing cultural and mental change. In this respect, the Annales's continuing engagement with theoretical developments across the human sciences in the postwar decades also played a part in the refinement and expansion of the range of study. Thus historical anthropology, the history of mentalities, and cultural history became the most impressive aspects of the contribution of the third generation of historians associated with the school. In all these areas, one can also point to congruent developments in historical approaches to the human sciences in postwar France, which paralleled the work of historians of the *Annales*. Toward the end of the century, even some of the most characteristic elements of the *Annales* approach were called into question by the practice of the third generation. Microhistory and case studies offered a contrast to the previous emphasis on the collective and the anonymous, while the resurgence of narrative history from the 1980s seemed to fly in the face of the reaction against *histoire historisante*, which had united the new history and the other human sciences, especially sociology, in the 1920s.

II

Febvre and Bloch were reacting against the historical positivism associated with Gabriel Monod, Charles Seignebos, and the *Revue Historique*, founded in 1876, but the French historiographical tradition was much wider and, since the Enlightenment, had produced philosophical histories, which sought to probe the underlying cultural and social factors of historical change. Voltaire's *Essai sur les moeurs* sought to place study of human behavior at the center of philosophical history. In the nineteenth century, a number of influential writers, including François Guizot, Alexis de Toqueville, and Jules Michelet produced wide-ranging analyses of the relationship between cultural and political change, which, in the case of the first two, owed much to Edmund Burke's development of a theory of society as the product of an essential historical process of organic institutional and social development. Michelet's breadth of interests ranged from cultural history to the history of the common people, and included the assertion that history must also be about the people and not just about power or institutions. Nevertheless, the influence of the scientistic mode of historical research associated with Leopold Von Ranke and the German school was evident in France after the defeat of 1870. History in the Third Republic was dominated by two main characteristics, one scientific, the other national. The first involved an admiration for the rigor of the German historical school, which Monod praised highly for its 'publication of documents, critique of sources, its patient elucidation of all aspects of history' (*Revue Historique*, I (1878), 315–316) and lay behind much of the academic organization of historical research led by Ernest Lavisse in the last decades of the nineteenth century. In the first issue of the *Revue Historique*, Monod proclaimed that the journal would be 'a collection of positive science and free discussion; moreover, it will not depart from the realm of fact and will be closed to political and philosophical theories' (*Revue Historique*, I (1878), 315–316). Although Monod showed himself open to a wider conception of historical knowledge held by other positivist historians, a more rigorously defined definition of historical science, which seemed to eschew most forms of intellectualism or generalization was evident in the *Introduction aux études historiques* published by Charles-Victor Langlois and Charles Seignobos in 1898. The great monument of this generation of historians was the multivolume history of France conceived by Lavisse in 1890 and published in 17 volumes between 1901 and 1911. The project was highly influential partly because of the academic credentials of the authors, but also because it provided a history that underpinned the political unity of the Third Republic. "Lavisse … created the myth of a nation-state, which came into being between the time of the Gauls and the Merovingians, was consolidated by the administrative changes and military conquests of the Capetian monarchy and culminated in an ideal constitution: the democratic, moderate, and centralizing Republic" (Bourdé and Martin, 1989: 209).

Bloch and Febvre emerged out of a reaction against this approach to history, which was increasingly criticized in the early decades of the twentieth century as limiting and partial. They were not alone in this critical approach to the reigning historical orthodoxy. Emile Durkheim criticized the focus on particular events as opposed to larger processes in the journal *L'Année sociologique* in 1896. But, wider perspectives were also being canvassed by historians around this time. In 1896, Henri Berr founded the *Revue de synthèse* in Paris bringing together a broad spectrum of scholars and intellectuals including psychologists, sociologists, economists, and historians, including Lucien Febvre. In his 1893 thesis *L'Avenir de la philosophie: esquisse d'une synthèse des connaissances fondée sur l'histoire* (The future of philosophy: outline of a synthesis of knowledge founded on history), and afterward, Berr saw historical synthesis as capable of providing a unifying and organizing element in all the sciences. Berr's regular seminars at the *Centre de synthèse* in Paris offered a model for the collective projects launched by Febvre and Bloch in *Annales* in the 1930s, although Berr's project was more theoretical in scope than the *Annales*. Febvre's first work was begun at the École Normale Supérieure in Paris where he encountered the geographer Paul Vidal de la Blache, founder of *Annales de géographie*. Febvre's first work was his thesis on *Philippe II et la Franche Comté* (1911) a regional monograph, which placed strong emphasis on the geographical, religious, and social history of the region. In *La Terre et l'évolution humaine* (1922), Febvre developed his ideas on historical geography and the interaction of humanity and the physical environment, 'seeking to understand the role in human history of a number of specifically geographical factors – distance, space, position.' Here Febvre signaled a concern with the spatial dimension of history, which was central to many of the future concerns of the school. During the 1920s, Febvre moved to the University of Strasbourg where he

was part of a brilliant group of scholars from many disciplines who reshaped the university in the aftermath of the First World War. Strasbourg was the scene of many fruitful exchanges between historians, sociologists, and anthropologists during the 1920s. Here also Febvre began his friendship with Marc Bloch. Bloch had also attended the École Normale Superieure and, like Febvre, had first completed a regional monograph, on the Île de France, published in 1913. Febvre and Bloch produced a number of major works in the 1920s and 1930s and both were appointed to chairs in Paris, Febvre at the Collège de France in 1933 and Bloch at the Sorbonne in 1936. In 1929, the two collaborated in founding *Annales d'histoire économique et sociale*. Febvre seems to have played the leading organizational role in the journal during the 1930s and took over completely when Bloch, who was Jewish, was excluded from academic life during the occupation. But both made ground-breaking contributions, both in the journal and in their books, during the interwar period. Two books in particular stand out as classics which, in separate ways, demonstrated the new approach to the history of mentalities, which was at the heart of their contribution. In *Les Rois thaumaturges* (1924) Bloch studied the phenomenon of royal healing in France over a long time frame, borrowing the concept of collective representations from sociology to analyze the belief system surrounding thaumaturgic kingship in the medieval and early modern periods. The result was an innovative study of the historical sociology of religious belief, which could perhaps be regarded as the first example of the history of mentalities, which was to be so prominent from the 1960s. Lucien Febvre's *Problem of Unbelief in the Sixteenth Century*, while primarily a study of Rabelais, was really addressing a more fundamental problem. Febvre disagreed profoundly with the standard current interpretation, which presented Rabelais as a free thinker and rationalist. Febvre's reinterpretation centered on stripping away anachronistic views of Rabelais's beliefs and reinstating the context of sixteenth-century belief and dissent. In arguing that Rabelais's mental universe could only be reconstructed within the terms and limits of possibility of the language and mental equipment of a sixteenth-century mind, Febvre gave an object lesson in the enlarged possibilities of an approach based on the reconstruction of the mental world of the past, including, in the case of Rabelais, the impossibility of atheism within the mental structures of the sixteenth-century mind.

The history of the journal in its early years reflected the concerns of the directors and especially Febvre, who contributed over 900 articles, reviews, and notices between 1929 and 1948. The battle against *histoire historisante* continued to be waged by Febvre in book reviews, which was also an important medium for pursuing the pluridisciplinarity of the journal. *Annales* also reflected Bloch's belief in the importance of delineating historical problems as the principal object of study, hence transcending the limitations of a fixed periodization. The sense of a relativity of historical time, with different rates of change and different time spans applying to different phenomena was clear, even if the subject matter was more familiarly historical compared to the *semaines de synthèse*. The first collective enquiry looked at the comparative history of land records across Europe. Business archives and price lists were studied in 1930. In 1935, there was a special issue on 'technologies, history, and life' and in 1936 an article 'les noblesses, reconnaissance générale' announced the launch of a collective enquiry on the nobility. During the war, when the journal changed its name, two new *enquêtes* were launched on alimentary habits and on associations in *ancien régime* society. The list alone conveys something of the excitement and the sense of possibility involved in extending the frontiers of research in so many new directions. Indeed Bloch's idea that the historian's craft involved the mastery of a vast range of disciplines made collective enquiry a practical necessity, as well as a reflection of his belief in the essential unity of the human sciences: 'there is only one human science in time, which strives incessantly to unite the study of the dead to that of the living.' The collective enquiries also reflected the journal's engagement with the contemporary world, and the explicit desire to use the new approach to history to cast light on some of the problems of the contemporary world in the aftermath of the Crash of 1929.

Although Febvre's work often concentrated on the study of individuals, albeit with a attention to deep contextualism, which anticipated later developments in intellectual history beyond France, he seems to have been more favorable to the increasing concentration on economic history, which grew in prominence in the 1930s and 1940s. Febvre saw the price surveys undertaken by François Simiand as a model for serial quantitative history, which would transcend the subjectivity of the documentary evidence and grasp patterns and recurring phenomena, which would reveal the deep structures of history. Bloch joined the resistance and was executed in 1944. He was succeeded at the chair of economic history at the Sorbonne by Ernest Labrousse, and this marked a turn away from the focus on the history of mentalities toward socioeconomic serial history. Febvre became more powerful after the war when in 1947 he set up the VIth section of the École Pratique des Hautes Études and director of the Centre des Recherches Historiques. The *Annales* school now had an institutional presence at the heart of French academic life, and its dominance was assured for the next four decades. Although never one of the directors, Ernest Labrousse was extremely influential in the direction taken by the work of the Annales historians from the 1940s to the 1960s. Labrousse's *Outline of the movement of prices and revenues in France* (1933) and his *Crisis of the French economy* (1944) provided a structure and a methodology, which was adopted by a whole generation of French historians. Pierre Chaunu called them 'the breviary of my generation' and saw them as more influential than even the work of Braudel. Labrousse introduced the idea of long-term trends and short-term crises and produced an interpretation of the long-eighteenth century and the French Revolution in terms of a century-long trend of rising prices, followed by a decade-long intercycle of contraction and a bad harvest of 1788 triggering the revolutionary events. Such a deterministic schema, clearly linked to Labrousse's Marxism, was very persuasive in the ideological climate of the 1950s, when many of the leading historians were associated with the left and, combined with the support of Braudel and the obvious affinities of Braudel's work with Labrousse's structural model, account for the leading place of quantitative history in the 1950s and 1960s.

More central than Labrousse, and far more wide-ranging and accessible as a historian, Fernand Braudel was Febvre's successor as leader of the Annales. Born in 1902, Braudel spent most of the period 1923–32 in Algeria, apart from 2 years in

Brazil. On Febvre's advice, he turned a conventional thesis on Mediterranean politics in the reign of Philip II into a study of the Mediterranean at the time of Philip II. The whole project took several decades to complete, the first draft written in a prisoner-of-war camp in Lubeck and the first edition published in 1949. The result was a monumental piece of scholarship, but also an innovative 'geohistory' with a radically new conception of historical time. Braudel wrote of 'les temps de l'histoire,' emphasizing the plurality of historical time. In this, he was following the Annales tradition of matching historical processes and phenomena to their specific durations, but also going much farther in presenting a total history of the Mediterranean as a series of overlapping or layered temporalities. In addition, Braudel wished to construct a geohistory, which would be attentive to space as well as time, recognizing the conditions of human society as intimately related to the landscape and emerging from the landscape in a series of overlapping developments corresponding to three major rates of temporal change. He was critical of the event-oriented history, which Febvre and Bloch had rebelled against, but also of a geography that suffered from analogous limitations when it neglected the environmental and temporal dimensions of human experience. He defined a geohistory as a task, which would 'construct a truly representative human geography; to make the geographers pay more attention to time (which should be fairly easy) and (what will be rather less easy) to make the historians more concerned about space' (Braudel, 1989a: ii, 295). The three times of history correspond to the three sections of *The Mediterranean*. The final section of the book deals with the time frame of conventional history, the short term, the *temps court*, where Braudel describes the political structures, wars, territories, and politics of the period. Braudel is less interested in these 'surface agitations,' 'oscillations,' 'surface disturbances, crests of foam that the tides of history carry on their strong backs.' These and many other comments reinforce Braude's hierarchical view of the relative unimportance of the short term, which is also, he points out, the time frame of the individual, but not of humanity itself. Braudel's distinction of times is also a distinction of rates of change. The short term is the time frame of rapid change, whereas the middle term is slower and rhythmical, 'a structural history, even a social history of groups and movements' what he also calls collective destinies. To this category belong networks of communication, systems of exchange, demographic trends, economic cycles of the kind described by Labrousse, and also the territorial empires of Spain and the Ottomans. Braudel's first level, corresponding to the opening section of the book, is the category of immobile, virtually timeless time. The processes of change at this level take place at a rate incommensurate with individual consciousness and yet they are, for Braudel, the most profound and inescapable forces in history. Understanding them involves an appreciation of human society as a phenomenon existing in and conditioned by the physical landscape and the environment – geology, soil, vegetation, climate, landscape, topography.

Braudel's concept of history as largely shaped by processes that are larger than humanity is fundamentally deterministic. It may be that his pessimistic view on the limitations of human agency and freedom ('a tiny island, a prison') may have been influenced by the fact that he was himself a prisoner when he first wrote the book. Unlike the possibilism of Vidal de la Blache, Braudel does not see the landscape as something that can be endowed with meaning, rather he seeks to see the human actors as shaped by forces emanating from the environment in ways that they cannot determine. Of course it is arguable that this consciousness is itself a means of humanizing the impersonal. Related to this determinism is the fact that culture is relatively neglected in *The Mediterranean*. Yet, despite criticisms, Braudel's massive work had an enormous impact on historical understanding. His assertion of the importance of the *longue durée* as the time frame, which enabled us to understand the relative importance (and unimportance) of human agency in the shorter time frames was nevertheless capable of supporting sophisticated analyses of historical processes in all three. His determinism was by no means reductive, but was rather an affirmation of the complexity of historical process, characterized by the interaction of forces operating at different levels of temporality and causation. It was not the great length of the work but its breadth which accounts for its enduring influence – the revelation of how the aspiration to a total history could provide a more rounded picture of the interaction between human society and the physical environment by expanding the field of historical enquiry in spatial and temporal dimensions. As well as taking over increasingly from Febvre in the direction of the school, through the VIth Section, the journal and the Collège de France, including inspiring and supervising a new generation of historians, Braudel produced two further major books, *Civilization and Capitalism*, a three-part work completed in 1980 and *The Identity of France*, an unfinished history of his own country published after his death. The first part of *Civilization and Capitalism*, *The Structures of Everyday Life*, again saw Braudel make a major contribution to extending the scope of history by focusing on the historical structures and forms of material culture, viewed in the perspectives of the *longue durée* and across continents. The study of material culture is now almost commonplace, indicating just how innovative and influential the book was. *The Wheels of Commerce* and *The Perspective of the World* studied the development of mechanisms of production and exchange, and then proceeded to describe the succession of dominant economic powers in the early modern period from Venice to the rise of Britain in the late-seventeenth century. Here again, Braudel's work was characterized by a combination of meditative insights, daring initiatives of interpretation and analysis based on the extended perspectives of the *longue durée*, and the incorporation of perspectives from across the human sciences, which cast fresh light on the evidence of the sources. Of course, the range of these sources had been dramatically increased by the fundamental reappraisal of the nature and significance of historical evidence associated with Annales. Epistemologically, the relationship between historical sources and historical knowledge was the same for Annales as for the scientistic historians of the previous century. What was fundamentally different was the range of sources discussed, the methodology of their use, the recognition of the need to apply the conceptual sophistication of other disciplines in the human sciences, and, thanks to Braudel and others, the demonstration that this would profoundly change our temporal and spatial understanding of the past. Braudel's example inspired Pierre Chaunu's monumental work on Seville and the Atlantic in the

early modern period, which revealed the power of the battery of methodologies assembled by the Annales.

To concentrate on the leading figures does not do justice to the breadth of the Annales achievement, or to its commanding role in French historical writing in the second half of the twentieth century. If the first and second generations can be conveniently assessed via Febvre, Bloch, and Braudel, the leading figure of the third generation, not least in terms of the international impact and popularity of his work, is Emmanuel Le Roy Ladurie. The 'Labrousse moment' and the dominance of Braudel were reflected in a preponderance of regional monographs based on serial quantitative methodology. Outstanding examples were Pierre Goubert's work on Beauvaisis in the early modern period, which was faithful to the Braudelian/Labroussian example, but also regional studies by Paul Bois and Maurice Agulhon, which restored the interest in cultural forms and mentalities, which Bloch and Febvre had displayed in the interwar period. Le Roy Ladurie's thesis, *The Peasants of Languedoc*, was also a regional monograph, which displayed the strengths of quantitative history in the *longue durée*, especially in the analysis of the interaction of Malthusian demographic structures and the rural economy, but where the standard model described a kind of homeostatic system maintained by short-term crises, Le Roy Ladurie's Languedoc traced a great cycle of recovery, stability, and decline from the mid-fifteenth to the end of the seventeenth century. More significantly, Le Roy Ladurie's analysis, while broadly comparable to the structural model of Goubert's Beauvaisis, did not describe an immobile history dominated by the impersonal interaction of structure and conjuncture, but interwove this with an account of the development of peasant society, which incorporated evidence of popular consciousness, including illuminating case studies of heresy and social unrest of the kind he later expanded into the best-selling *Montaillou*, a historical anthropology of a Cathar village, and *Carnival at Romans*, a case study of the breakdown of social relations in an urban setting, which became a microcosm of early modern urban mentalities and behavior. The range of Le Roy Ladurie's work was in some ways Braudelian, as in his study of the history of climate since the year 1000, comparable to the global perspectives of Braudel's *Capitalism*, but also represented a rediscovery of the specific and the short term, which had been in danger of becoming obscured by an excessively programmatic focus on the quantitative and the impersonal. The case studies reflected an awareness of further waves of affinity in the human sciences in cultural anthropology and cultural theory associated with writers like Pierre Bourdieu, Marcel Mauss, and the slow impact of Norbert Elias. What Michel Vovelle half-jokingly called the bulimia of historians ensured that the danger in all schools of creating a sterile orthodoxy was subverted by the constant evidence of creativity in addressing problems and sources, and a continued willingness to listen to others, including other historians. Was the fertile interaction between Annales and non-Annales historians from the 1960s a reflection of the success of the school in redefining the objects and nature of historical enquiry? Certainly, the thoroughly original contributions of Philippe Ariès and Michel Foucault on death, childhood, madness, prisons, and the epistemic structures of historical systems of thought all posed a challenge to Annales and yet a validation of the notion that history would proceed by identifying and illuminating important areas of research and enquiry, which were the subject of important reflections across the human sciences. For the Annales school, the response was to grapple with the questions of how historians could contribute to this kind of historical anthropology, what kind of sources could be identified, and how should they be studied. Michel Vovelle's study of attitudes to death, the afterlife, and religion, *Baroque Piety and Dechristianisation* (1973) owed much to the work of the Catholic religious sociologist Gabriel Le Bras, but Vovelle's background was as a Marxist and follower of Labrousse's approach to serial history. Vovelle's study of changing religious attitudes in eighteenth century Provence was based on a study of 30 000 wills – a forbidding kind of documentation whose potential he dramatically revealed and in doing so also showed that an austere quantitative approach could be fruitfully applied to the history of mentalities, which once again occupied a central place in the Annales, and could build on its sophisticated tradition of intellectual innovation, which did not sacrifice historical rigor. Collective enquiries were organized into attitudes to death and popular literacy from the 1970s onward and these in turn provoked a further refinement of the problematics of analyzing cultural phenomena through historical sources. Adopting perspectives from cultural theory, Roger Chartier's work on cultural history suggests a further refinement of the development of the study of mentalities by emphasizing the primacy of cultural and symbolic constructions. Peter Burke, who was one of the earliest British historians to appreciate the significance of the Annales, and who has been a constant innovator himself, and André Burguière, an Annales insider who has written an intellectual history of the movement, see the revival of narrative, the reemergence of mentality (as historical anthropology), and the revival of interest in politics as key themes in the development of Annales since the late 1980s. Burke, writing in 1990, saw the divergence of themes and approaches as evidence of continuing vitality but queried whether it was still possible to speak of an Annales school because of its achievement in transforming history internationally as much as because of the divergences of the fourth generation: 'the movement is dissolving, in part as a result of its success' (107). Both Burke and Burguière, writing in 2006, agreed on the centrality of the return to mentalities for the relationship between history and the human sciences, and outlined the challenges faced by historians in responding to some of the demands of cultural theory and anthropology, still facing the problem confronted by the founders of *Annales* between the individual agent and the collective consciousness.

Abstract

The word 'anomie' comes from the ancient Greek *anomia*, meaning absence of rules, norms, or laws, and is still sometimes used in this highly general sense. The term 'anomie' was reinvented by Jean-Marie Guyau, but it was Emile Durkheim who inscribed the term in the vocabulary of sociology. In *The Division of Labor in Society* (1893), Durkheim called 'anomie' an abnormal form of division of labor, defining it as the absence or insufficiency of regulations necessary to ensure cooperation between specialized social functions. In *Suicide* (1897), anomie (whether economic or conjugal) refers to the insufficient social regulation of individual aspirations: the indetermination of the object of the desire leads to frustration. Anomie underwent American naturalization in the 1930s at Harvard University. Merton's 'Social Structure and Anomie' metamorphosed the concept: Durkheim's anomie refers to the lack of restriction on goals; Merton's anomie refers to restriction on means. This semantic revolution attained its full effect between 1955 and 1970, in sample surveys that used attitude scales designed to measure the psychological counterpart of social anomie. At that time 'anomie' came to be considered the sociological concept *par excellence*, despite (or because of) the semantic confusion surrounding it.

'Anomie' comes from the ancient Greek *anomia*, meaning absence of rules, norms, or laws (the adjective form *anomos* was more common). The word is still sometimes used in this highly general sense. In Greek thought it had negative connotations of disorder, inequity, and impiety; and when it reappeared briefly as 'anomy' in English theological literature of the seventeenth century (Orru, 1987), its meaning was somewhat similar to the ancient Greek usage of the word. The term came back at the end of the nineteenth century in the writings of French philosophers and sociologists. The French spelling imposed itself in the language of English sociology despite attempts to anglicize it to 'anomy.' 'Anomie' was particularly popular among American sociologists in the 1960s. It is one of the few lexical inventions in sociology, perhaps the only one, which has been specific to the sociological community. But sociologists used it with differing and even contradictory meanings – sometimes without any meaning at all – and its career eventually ended in total confusion.

Durkheim's Concept

'Anomie' was reinvented by Jean-Marie Guyau, a French philosopher with a sociological bent, in two books: *Esquisse d'une morale sans obligation ni sanction*, published in 1885, and *L'Irréligion de l'avenir*, published in 1887. Guyau opposed *anomie* to *autonomie* (Kantian autonomy). Because of the progressive individualization of the beliefs and criteria for ethical conduct, the morality of the future would be not only autonomous but anomic – determined by no universal law. For Guyau this process was both ineluctable and desirable.

After Guyau, the word appeared occasionally in late nineteenth century, in the writings of French philosophers and sociologists, such as Gabriel Tarde. But it was Emile Durkheim who would inscribe 'anomie' in the vocabulary of sociology, the new discipline he intended to found.

Durkheim could not accept Guyau's anarchizing individualism since for him every moral fact consisted of a sanctioned rule of behavior. He therefore considered anomie a pathological phenomenon. In *De la division du travail social* (*The Division of Labor in Society*), his doctoral thesis defended and published in 1893, Durkheim called anomie an abnormal form of the division of labor, defining it as the absence or insufficiency of the regulation necessary to ensure cooperation between different specialized social functions. As examples of anomie he cited economic crises, the antagonism between capitalists and workers, and science's loss of unity due to its increasing specialization. In all three of these cases, what was missing were continuous contacts between individuals performing different social roles, who did not perceive that they were participating in a common undertaking. At the end of his chapter on anomic form, Durkheim discussed another kind of pathological characteristic of industrial societies: the alienation of the worker performing an overspecialized task. This explains why a number of Durkheim's readers understood job meaninglessness to be an integral part of anomie. In fact, they introduced a 'parasite' connotation into his concept. Such alienation is not only different from anomie, it is in many ways its opposite.

Durkheim further developed the theme of anomie in *Le Suicide* (*Suicide*) (1897), defining anomic suicide as that resulting from insufficient social regulation of individual aspirations. In this connection, he discussed economic anomie, caused by a period of economic expansion; and conjugal or sexual anomie, due to the introduction and spread of divorce. In both these cases, an opening up of the horizon of the possible brings about the indetermination of the object of desire, or unlimited desire (which amounts to the same thing). This leads to frustration. The anomie that follows a passing crisis may be acute, but Durkheim was especially interested in chronic, even institutionalized anomie. This type of anomie, the 'morbid desire for the infinite,' was an unavoidable counterpart of modern industrial society, residing simultaneously in its value system, e.g., the doctrine of constant

[†] Deceased; updated and refreshed by Douglas Massey.

progress; its institutions, e.g., divorce law; and its functioning, e.g., competition in an ever-expanding market. However, along with 'progressive' anomie, Durkheim also evoked a 'regressive' type, which actually pertained to 'fatalism.' This last notion, which Durkheim did not really develop, refers to the impossibility of internalizing rules considered unacceptable because they were unjust or excessively repressive. Here, desires and aspirations run up against new norms, deemed illegitimate; there is a closing down of possibilities. This situation is in fact the opposite of progressive – true – anomie, where the wide, open horizon of the possible leads to unlimited desires. Fatalism, then, is the opposite of anomie, just as altruism is the opposite of egoism (Durkheim's terms for the other types of suicide). In fact, this bipolar theory of social regulation of aspirations was not clearly laid out by Durkheim, and this no doubt explains the concept's peculiar later career. After Durkheim, 'anomie' underwent a complete semantic revolution.

Anomie was not a permanent theme in Durkheim's thought; he was more concerned with the question of social integration. Indeed, both word and concept disappeared from his work after 1901 and they are not to be found anywhere in the works of his disciples or collaborators in the 'French school of sociology' and in *L'Année sociologique*. In *Les Causes du suicide*, a purported continuation of Durkheim's study of suicide published in 1930, Maurice Halbwachs confirmed Durkheim's results on many points; but he either neglected or rejected everything that could possibly pertain to Durkheim's theory of anomie, he made no reference to conjugal anomie, and he refuted Durkheim's hypothesis of a progressive economic anomie.

Yet it was in the sociology of suicide, particularly in American studies of the subject, that Durkheim's notion of anomie would endure for a time, following the 1951 English translation of *Le Suicide*. In this connection, mention should be made of Henry and Short's (1954) study, in which they sought to apply Durkheim's concept of anomie to their analysis of the effect of the economic cycle on suicide frequency. The largely negative results of this and other tests of Durkheim's progressive anomie hypothesis did not encourage sociologists to explore this avenue of research further. Conjugal anomie, meanwhile, was left almost entirely aside in suicide studies, which gave primacy to Durkheim's egoistic suicide, reflecting a preference for his theory of integration over the less developed one of regulation.

The Americanization of Anomie

As with sociological studies of suicide, the future of 'anomie' was linked to American sociology's reception of Durkheim's work, particularly *Suicide*. Interest in Durkheim began to manifest itself only in the 1930s. With the notable exception of Parsons (1937), however, little attention was paid at first to 'anomie.' The term made little headway at the University of Chicago, where a tradition of research on social disorganization had developed in the 1920s, though Louis Wirth (1938) famously argued that the size, scale, and heterogeneity of cities would inevitably produce anomie in urban society. It was at Harvard University that 'anomie' underwent its American naturalization. Used by Elton Mayo (1933), Talcott Parsons (1937), and Robert K. Merton (1938), it appeared as a new label – and possibly a new theoretical framework – for the study of social disorganization and deviant behavior; and enabled the new department of sociology at Harvard to position itself in relation to the old Columbia–Chicago struggle for intellectual supremacy in the discipline. This strategic aspect may be seen in the young Harvard theoreticians' use of the French spelling (sociologists at Columbia, like Durkheim's translators, spelled it 'anomy'). Distinguishing themselves from the American tradition and appropriating the continental European one, that of Durkheim, Weber, and Pareto, the Harvard sociologists spelt the term as 'anomie.'

Merton's successful *Social Structure and Anomie* in its various versions (1938, 1949, 1957, 1964) both made the term familiar and metamorphosed the concept. In fact, Merton never clearly defined what he meant by anomie. We can nonetheless say that Merton's theory ultimately identified anomie as the contradiction between the culturally defined goal of success and the individual's lack of access to legitimate means of achieving this goal. To resolve this contradiction, the individual may engage in deviant behavior, one form of which is using illegitimate means. Merton called this mode of adaptation 'innovation.'

Merton's theory of anomie is fairly equivocal, but it was understood and used as a theory of differential access to the means to success, one which predicted that delinquent behavior was most likely in the least privileged social strata. This theory, which reached its apogee in the mid-1960s, has been considered the core of the 'Strain Theory,' a major sociological approach to deviance. It should be noted that Merton's theory was only rarely tested in empirical research on delinquency and that when it was, the results were generally negative.

The Mertonian concept of anomie – to the extent that its content can be identified and as it has been generally understood – is in many ways not only different from Durkheim's anomie but opposed to it. The opposition was not perceived at the time because Merton never related his own use of the term to Durkheim's. Durkheim's anomie is about the lack of restriction on goals; Merton's anomie refers to restriction on means. In Merton's theory, goals are given, defined, even prescribed by the cultural system, whereas for Durkheim the central feature of anomie is indeterminacy of goals. Durkheim's anomic individual is uncertain of what he should do because the horizon of possibilities is so open; whereas for Merton that individual, with the clearest of ideas of the objective to be reached, finds the possibilities for success closed down.

This semantic revolution attained its full effect in American sociology between 1955 and 1970; There were numerous sample surveys using attitude scales designed to measure the psychological counterpart of social anomie. This research in turn was based on theoretical essays in which anomie had appeared for the first time outside Harvard: at the end of the 1940s sociologists and political scientists such as David Riesman, Robert MacIver, and Sebastian De Grazia had psychologized the concept, using the word 'anomie' to designate individual feelings of anxiety, insecurity, and distrust. These feelings figured in 'anomie scales,' meant to measure the degree of pessimism in world views, feelings of having no control over one's situation, and the renunciation of hope. The most famous of these was developed by Leo Srole in 1956 and called the 'anomia scale.' In Durkheim's thought, these phenomena were

characteristic of fatalism – the opposite of anomie. Anomie had become interchangeable with the notion of alienation, which sociologists were trying to apply in attitude scales; normlessness had been associated with powerlessness. All these empirical studies using attitude scales were based on the (mistaken) postulate of a single unified concept of anomie: the myth of a continuous tradition of research, with Durkheim as precursor and Merton as prophet.

Anomie scales were contemporaneous with the other main usages of the term. As we have seen, it was between the mid-1950s and the late 1960s that 'anomie' was most heavily used, in its Durkheimian meaning, in the sociology of suicide; and with its Mertonian meaning (mainly) in the sociology of deviant behavior. That contradictory meanings of one and the same term should have been successful at the same time shows that the function and use of the word 'anomie' in sociology was more decorative than cognitive.

In the 1960s, anomie came to be considered the sociological concept par excellence, despite (or because of) the semantic confusion surrounding it. In the 1968 edition of the *International Encyclopedia of the Social Sciences*, Talcott Parsons explained that anomie was one of the few concepts truly central to contemporary social science. At that time the term had reached the peak of its glory. Because 'anomie' made possible a kind of bridge between references to classic theoretical sociology and sample surveys using attitudes scales purporting to test hypotheses drawn from those theories, it served as the emblem of the dominant research practice of the time (opposed to the ecological analysis and fieldwork favored by the Chicago School).

Though the word 'anomie' has lost much of its attraction for sociologists, some still use it rather vaguely to mean deregulation or disorder. It would be preferable to restrict usage of the term to Durkheim's meaning of an excessive growth in aspirations or expectations. This concept refers to a paradox present in Tocqueville as well as in the notion of relative deprivation, for which Raymond Boudon (1977), constructed a model: when individual objective conditions improve, collective subjective dissatisfaction may increase.

Recent Departures

Whereas Wirth (1938) drew on Durkheim and other classical theorists to predict rising anomie as society urbanized, Fischer (1975) argued that what Wirth observed in cities was not deviance stemming from a state of anomie, but a high rate of unconventional behavior stemming from the proliferation and intensification of subcultures within large, dense, and diverse urban settings. Subsequent evidence indeed showed that people engaging in unconventional or 'deviant' behaviors were not suffering from an absence of values, but in fact were well integrated into the values of specific subcultures that validated and sustained their behavior – behavior that only appeared 'deviant' relative to mainstream actors but not to members of the subculture (Fischer, 1995). Thus urban society was not disorganized, but very well organized into different, partially overlapping, and partially competing subcultures.

The latest incarnation of Merton's conceptualization of anomie as stemming from a gap between legitimate goals (e.g., earning money) and access to the legitimate means to achieve them (e.g., access to high-paying jobs) is Messner and Rosenfeld's (2006, 2007) theory of institutional anomie, which argues that in contemporary societies the market has been allowed to dominate over other institutional spheres, such as the family and the polity, to create an imbalance in values that leads to a particularly criminogenic form of anomie, a view that finds considerable support in recent work. Baumer and Gustafson (2007) show that crime rates are significantly greater in areas where a strong commitment to monetary success coexists with a weak commitment to legitimate means of getting ahead. Burkatzki (2008) finds that the willingness of people to subordinate the common welfare for individual economic success rises as actors become more integrated into the market sphere; and Bjerregaard and Cochran (2008) demonstrate that homicide is strongly predicted by a three-way interaction between GDP (gross domestic product), economic freedom, and income inequality. In general, anomie rises during periods of rapid social change and is less likely among those of higher socioeconomic status, who are buffered from the negative effects of social, economic, and political change (Zhao and Cao, 2010; Legge et al., 2008).

Anomie: History of the Concept

Mathieu Deflem, University of South Carolina, Columbia, SC, USA

Abstract

Anomie is a term that, in various forms, originally appeared in writing in Greek antiquity and biblical history. Introduced in modern sociology by means of an appropriation from social and moral philosophy at the end of the nineteenth century, the concept of anomie was first applied in the seminal works of Emile Durkheim. It was subsequently elaborated and examined in the context of the sociology of deviant behavior on the basis of the writings of Robert K. Merton. With varying levels of success, anomie has remained a mainstay in sociological theory and research until today. The meaning of anomie has thereby undergone several transformations of more and less conceptual significance.

The term anomie dates back, in slightly differing linguistic forms, to Greek antiquity, the biblical writings of the Old and New Testaments, and late-nineteenth-century philosophy. As a scientific concept, anomie was introduced in sociology by Emile Durkheim and subsequently popularized through the writings of Robert K. Merton and other scholars working from within the tradition of structural-functionalism. Yet, Durkheim and Merton were not the only scholars to have developed sociological and other theories related to the term. Over the course of the development from classical to modern sociology, moreover, the concept has been used in a number of ways, both more and less distinctly related to the seminal works of Durkheim and Merton. A resurgence of the concept of anomie can be noted since the end of the twentieth century. As a result, in the contemporary sociology of the beginning of the current millennium, multiple understandings of the concept of anomie and related theories coexist.

Anomie Before Sociology

The concept of anomie is not the invention of sociology, but is a term that has historically existed in various incarnations dating back to ancient Greece (Orrù, 1987). Etymologically, the concept is derived from the Greek '*anomia*', which, containing the root term '*nomos*', literally means a lack of law or, more broadly, deregulation and/or normlessness. As first introduced in Greek antiquity, the term not only refers to a factual state of affairs, denoting a lack of order, but also carries with it an ethical judgment of the undesirability of that condition. Thus, typical of a society's culture that is as yet undifferentiated into scientific, ethical, and aesthetical realms, anomie was in the Greek tradition at once a descriptive and normative term, presenting both a rudimentary sociology and a philosophy of society.

Specifically, Greek philosophy contained references to *anomia* during debates in the fifth-century BC, which, foreshadowing modern sociological debates on anomie, was a period in history marked by profound social changes and turmoil. Greek philosophers in the sophist tradition that was oriented at educating political leaders and members of the nobility differentiated at least three aspects of these changes in qualifying a person as 'anomic', referring to a lack of personal character (inhumaneness), a disregard for religious norms (impiety), and defiance toward the unwritten rules of traditional custom (injustice). The Greek term *anomia* was mostly referenced in its adjective form (*anomos*) to relate to an order of rules and norms broader and more fundamental than only formal laws. The social and ethical problems discussed were therefore of both a moral character and political in nature, affecting people's dispositions and conduct as well as the social order in which human relations were organized. *Anomia*, in other words, was held to be a quality existing in people as well as in the order around them.

A next important presociological step in the development of the concept of anomie is its treatment in the biblical writings of Judaism and Christianity (Orrù, 1987). The biblical usage of *anomia* was partly influenced by relevant Greek philosophical writings because it entered the biblical tradition when the Old Testament was translated into Greek. Initially, the word *anomia* was used for about 20 Hebrew words, referring to various aspects of wickedness, ungodliness, injustice, wrongdoing, evil, depravity, transgressions, and sin. In the latter meaning of sin, *anomia* was used interchangeably with the Greek term '*hamartia*' which refers to a fatal flaw. The biblical understanding of *anomia* gradually became more delineated in meaning to refer, not to individual shortcomings, but to a state of society whereby the forces of evil took control over and against the divine order during the last days of the world. This apocalyptic understanding of *anomia* bears some resemblance to the sociological notion of anomie Durkheim would introduce in the late-nineteenth century as a counterpart to Karl Marx's historical-materialist theory of alienation.

A third understanding of anomie before the coming of sociology was represented in certain religiously inspired strands of Western philosophy, specifically in sixteenth- and seventeenth-century England, which developed a conception of natural law based on selected aspects of ancient Greek thought. This renaissance recaptured the Greek notion of *anomia*, which had mostly vanished during the Middle Ages, in legal as well as biblical writings by means of the Anglicized word 'anomy'. A perspective of natural law was thereby proposed in which the lawlessness of anomy was situated in opposition to an order that defended a sense of nature with implications for both the religious order and the social world. This understanding of anomy, however, was not successful in inspiring further

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03067-1

developments of philosophical and social thought. Stripped of its religious connotations, a new theory of anomie would not be developed until the late-nineteenth century.

Anomie in Classical Sociology

The French sociologist Emile Durkheim was the first to introduce the concept of anomie and a related theory of society into the discipline sociology, but he did not independently reinvent the term. Instead, Durkheim had discovered the concept of anomie first in the writings of his philosophical compatriot Jean-Marie Guyau (Besnard, 1987; Orrù, 1987). A prolific writer on moral theory, Guyau had written six books and an additional three manuscripts by the time of his untimely death at 33 years in 1888. Guyau's French-language concept of '*anomie*' appeared in two of his books, dealing with religion and morality, and was directly derived from the Greek '*anomia*', a term Guyau mentions explicitly in his writings. Interestingly, Guyau does not conceive of anomie as a sign of evil, but as the distinguishing quality of an epoch whereby the decline of religious traditions has brought about a continued individualization of morality and rules. Under conditions of freedom, a morally good social order can only mean the absence of collective order and obligation.

When Durkheim reviewed Guyau's work in the 1880s, he favorably commented on its ability to develop elements of a sociology of religion, manifested in Guyau's observations on the decline of religious traditions over the course of history. But Durkheim refuted Guyau's individualistic moral anarchism in favor of developing an understanding of anomie as being in contraction with a society's morality, the foundations of which to Durkheim could only be social, not individual. Thus, in Durkheim's sociology, morality is equated with social order, and any profound disturbance of the social order is captured under the heading of anomie.

Durkheim discussed the concept of anomie in two main instances in his sociological work (Besnard, 1987; Deflem, 1989). In his 1893 book on the social division of labor, Durkheim (1893) defends the perspective, squarely oriented against Marx's theory on the inherent contradictions of capitalism, that the division of labor under normal societal circumstances does not produce any negative outcomes. However, under exceptional circumstances, Durkheim argues, the division of labor that marks society as a whole produces pathological or anomic outcomes because and when, first, there are no regulatory bodies to oversee the process and direction of the division of labor and, second, the actions of such bodies are not prespecified by a particular set of rules. Durkheim mentions three such instances of an anomic division of labor taking place: during sudden periods of economic crisis; when conflicts occur between labor and capital; and with the increasing specialization of the moral and social sciences. In these cases, there is either no sufficient regulation over social relations or existing regulations are not congruent with the degree of societal development. The underlying theoretical premise of this concept of anomie as deregulation is that in so-called organic societies, with which Durkheim refers to modern societies that are marked by a high degree of individualism and functional specialization, integrative mechanisms are needed to accomplish unity and order through an appropriate recognition of diversity. According to Durkheim, the central organ necessary to achieve this integration and avoid anomie is the government as it can formally administer all necessary laws for a national collectivity.

In his seminal study on the social conditions of suicide, Durkheim (1897) also relies on a notion of anomie as part of a general theory of society, which he develops to account for various forms of suicide as a social fact. Distinguishing different types of suicide at the aggregate level, Durkheim first differentiates altruistic from egoistic suicide to refer to suicides influenced by the two extreme conditions of social integration. Egoistic suicide results from an insufficiency or lack of integration, while altruistic suicide is brought about by an extreme excess of integration. The consistently higher suicide rate among Protestants as compared to Catholics is an example for the former type, while the higher suicide rate in the military as compared to civilian life is an example of the latter.

A third form, anomic suicide, Durkheim explains on the basis of an absence or a weakening of social regulation. Under these circumstances of inadequate or ineffective regulation, the suicide rate is abnormally high because of the suddenness of the changes taking place, irrespective of whether those changes are perceived as beneficial or harmful. Examples include moments of economic crisis, divorce, and rapidly acquired political strength through military expansion. Underlying Durkheim's concept of anomie is the theory that social rules are needed in order to limit human desires that otherwise would be insatiable. Therefore, according to Durkheim, society, which exists exterior to the individual, holds a favorable coercive force over the individual's desires. Under exceptional circumstances, including both fortunate and unfortunate but always sudden moments of transition, societal constraints are not effective in regulating human conduct. Acute forms of anomie then ensue, raising the level of suicide to pathological levels. Additionally, Durkheim argues, that in some spheres of social life, specifically in the realm of the economy, an absence of regulation can be of a more chronic nature. In such cases of a materialistically driven lack of any restraint, the anomic suicide rate is consistently high. The type of fatalistic suicide that results from an excess of regulation, as a logical counterpart to anomic suicide, Durkheim considered only a theoretical possibility. Also, anomic conditions could according to Durkheim only be effectively dealt with by means of well-functioning corporations or professional groups that, positioned in between singular individuals and the whole of society, can take on important regulatory functions.

Anomie and Deviant Behavior

Durkheim's concept of anomie did not readily lead to develop a relevant strand of empirical research and theorizing, although the classic's underlying theory of society was, of course, enormously influential in the further evolution of sociology in the modern era. Neither did a corresponding Durkheimian sociology of law and norms develop until more recent times of advanced sociological specialization. However, Durkheim's concept of anomie would be reintroduced in modern sociology by way of the intellectually closely aligned emergence of

American structural-functionalism and its attention toward social integration and regulation. The modern concept of anomie would thereby change in meaning and become associated more closely with the sociology of deviant behavior.

Robert K. Merton performed the most valuable work to renew and popularize an interest in anomie when he developed a novel sociological perspective of deviant behavior. Merton's initial version of this theory was published in 1938 at a time when the scholar was heavily influenced by Durkheimian thought while a student at Harvard (Merton, 1938). That initial paper was a rather exploratory sketch of a theory on the social conditions of deviant behavior, which he subsequently presented in a more systematic fashion (Merton, 1949), and elaborated with an additional chapter that was published, along with the theory's mature version, in the 1957 edition and all subsequent versions of his influential collection of papers, *Social Theory and Social Structure* (Merton, 1957a,b).

Merton's theory of anomie is presented as part of a sociological approach to the study of deviant behavior. Merton developed this perspective with the manifest objective of producing a sociological theory that conceived of deviant behavior as the normal outcome of certain social conditions, rather than an aberration on the basis of a psychology or biology of criminal dispositions. Merton's theory unfolds on the basis of a perspective of society that distinguishes between the cultural goals preferred in a given social context, on the one hand, and the institutionalized norms or legitimate means to pursue those objectives, on the other. This viewpoint is applied to the conditions that exist in the context of the United States, whereby, Merton argues, the predominant goal is individual success, especially in the form of monetary wealth, while the institutionalized norms in the American context value hard work, especially by means of education and employment. Merton additionally observes, on the force of corroborating empirical evidence, that the cultural objectives of American society are typically emphasized much more than the legitimate means to reach them, thus unsettling the equilibrium between goals and means. As a result of this disjunction, Merton argues that anomie or normlessness takes place in the form of a deinstitutionalization of the legitimate means of society.

Merton's related, but otherwise distinct theory of deviant behavior explains the various modes of conduct that can take place under conditions of anomie (Featherstone and Deflem, 2003). Merton maintains that anomic conditions place specific pressures on individuals in terms of their ability to adopt cultural goals and means, which varies according to their respective positions in the social structure. Several modes of adaptation are possible, the most common one being conformity, whereby both the goals and means of society are accepted. Other forms of conduct, however, are considered deviant (although not necessarily dysfunctional) and involve an inability to adopt culturally approved goals and/or institutionalized means. In the case of innovation, for instance, alternative and often illegal means are appropriated to attain the cultural goal of individual success and monetary gain, whereas the adaptation of ritualism implies a holding on to legitimate means even though the success goals are out of reach. Developing a related theory of opportunity structures (Marwah and Deflem, 2006), Merton maintains that the likelihood of various adaptations is influenced by the extent to which individuals do or do not have access to legitimate means in pursuit of widely shared goals. Merton in this respect referred to economic as well as cultural and other relevant conditions of opportunity.

It can readily be observed that Durkheim's and Merton's concepts of anomie are not identical, as the former primarily relates to a society's goals, whereas the latter emphasizes varying opportunities of means. However, unlike Durkheim's original notion, Merton's reintroduction of the anomie concept in modern sociology brought about a veritable avalanche of research and theory, especially in the realm of the sociology of deviant behavior and crime in the post–World War II era, with several hundreds of articles and books devoted to the subject until the 1970s. Of special interest are efforts to measure anomie empirically and related attempts to extend the notion of anomie from describing a state of society to analyzing the conditions of individuals in anomic societies (Deflem, 1989). Most famous among the attempts to operationalize anomie is a scale developed by Leo Srole to measure the subjective experiences of people exposed to the social condition of anomie. Because Srole was aware that this measure did not capture anomie as a social condition, but instead examined the attitudes and dispositions of individuals, he reintroduced the corresponding term anomia in a sociopsychological meaning. Relatedly, other modern sociologists who were influenced by Merton's writings, but who were also conscious of a growing theoretical awareness to distinguish between macro and micro aspects of social life, likewise argued for the relevance of the psychology of anomie to conceptually differentiate the subjective experience of anomie from its objective conditions. With variable levels of success, and causing some unneeded terminological confusion, the term anomie was then substituted by, and/or interchangeably used with, anomia and anomy. In the present era, however, only the concept of anomie has survived.

Besides the microtheoretical readings of anomie, conceptually most interesting during the period of the dominance of American structural-functionalism was the effort by mastertheorist Talcott Parsons to explore anomie within a broadly Durkheimian framework. In his first major work, *The Structure of Social Action*, Parsons (1937) explains the notion of anomie as central to Durkheim's thought in revealing that the coercive force of society over the individual, unlike the physical force of nature, is moral in kind. This insight leads Parsons to develop, and argue for the gradual unfolding in Durkheim's work of, a voluntaristic theory of action, whereby the human will is seen as central to the functioning of society. Anomie, conversely, denotes a breakdown of the hold of norms over individual conduct. In *The Social System*, Parsons's (1951) second *magnum opus*, the concept of anomie is again introduced in a Durkheimian fashion, albeit with explicit reference to a sociological theory of deviant behavior and social control. Critically responding to the writings of his former student Robert Merton, Parsons uses the concept of anomie to refer to a state of disjunction between expectations and reality, involving a breakdown of the social order in the form of an ineffective regulation of human conduct. Anomic forms of suicide and deviant behavior are the result of this state of anomie. Mechanisms of social control are then called

upon to restore the social system. If social control is not successful, anomie may endure to the point where structural changes lead the way to a different collective order.

Contemporary Travels and Adventures of Anomie

With the decline of the dominance of structural-functionalist sociology during the 1970s, the concept of anomie had all but vanished from sociology, especially from the practice of social research where once it had gained a central place. However, by the late 1980s, as the vulgar criticisms against structural-functionalism had been scrutinized and at least partly overcome, the concept of anomie witnessed something of a resurgence that has lasted, and has even been strengthened, until this day. At least two currents can presently be discerned in contemporary sociological perspectives of anomie.

First, the Mertonian concept of anomie has remained of considerable interest in contemporary criminology and sociology (Alder and Laufer 1995; Marwah and Deflem, 2006; Passas and Agnew, 1997). The attention has shifted, however, toward treating Merton's contributions as a classic reference point, rather than a direct source of research, and toward the further exploration of Merton's theory of deviant behavior rather than the theory of society, as comprising cultural goals and institutionalized norms, that Merton developed along with it. Thus, the attention has moved away from anomie theory toward strain theory, whereby the latter dimension is often explored in individualistic terms. An exception, adequately focusing on the structural dimensions of society that are central to Durkheim, Merton, and like-minded sociologists, is the perspective of institutional-anomie theory that focuses on the criminogenic impact of the relative lack of regulation of an unbridled free-market economy by regulatory institutions such as the family.

Second, the concept of anomie has reappeared in contemporary sociological discourses in a meaning that relates more distinctly to the concept Durkheim originally introduced. Some of these efforts are of a theoretical nature, but most are explored through empirical research. On a theoretical level, among the noteworthy reintroductions of anomie is the work of Jürgen Habermas, specifically his sociological theory of system and lifeworld. Foregoing a lengthy exposition of this theory of society, Habermas (1981) introduces a concept of the lifeworld that refers to the dimension of society where actors are meaningfully coordinated in their social relations through communicative action. Habermas posits that the lifeworld contains the three structural components of culture, society, and personality, which, respectively, serve the functional needs of cultural reproduction, social integration, and socialization. Habermas describes the problems that can occur with respect to these three functions as, respectively, a loss of meaning, anomie, and psychopathologies. This Habermasian understanding of anomie is thus closely akin to, and directly derived from, the concept as it was introduced by Durkheim.

More elaborate than the odd theoretical elaboration of anomie in contemporary sociology are the many new lines of empirical research that have used the concept of anomie in recent decades. This new and still growing literature on anomie is oriented at describing and analyzing issues of deregulation, normlessness, and/or norm-ineffectiveness that have come about since some of the most major societal changes that took place during and since the end of the twentieth century, such as the fall of communism, the global spread of capitalism, and the diffusion of, and difficulties involved in implementing with, the ideals of democratic government. Particularly noteworthy are the instances of social research on anomie in the context of post-Communist Eastern Europe and along with the rapid modernization of China. In the European context, important societal changes relevant to the study of anomie are additionally brought about by the encroachment of the European Union and the high levels of immigration into the European continent. In the Chinese context, the coexistence of a still Communist political regime with a rapidly modernizing economy has been observed to have produced strains and discrepancies in the social system that bring about a form of disorder the concept of anomie can highlight. Finally, there are some, albeit as yet few signs that the concept of anomie has gradually also begun to gain some new attention in other sociological studies, especially at the level of organizations. A veritable revival of anomie cannot yet be predicted at the present time.

Anthropocene Epoch

Anson W Mackay, University College London, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The Anthropocene, as a geological term and disciplinary concept, has gained widespread acceptance in recent years. It represents the period of time when humans have had major, global impacts on many of the Earth's systems (e.g., atmosphere, oceans, and terrestrial biospheres), post AD 1800. The extent of human impact on the Earth is initially discussed, followed by events characterizing the start of the Anthropocene and the Great Acceleration after the end of the Second World War. Increasing greenhouse gases, ocean acidification, and biodiversity loss are considered in detail as case studies.

The Anthropocene: The Beginnings

It has been recognized since at least the middle of the nineteenth century that human activities have had major environmental impacts on the Earth (Marsh, 1864) and its atmosphere (Smith, 1872). At this time, the Western nations were undergoing a revolution in technological innovations, linked primarily to the efficient exploitation of stored energy in fossil fuels: the Industrial Revolution. Fossil fuels provided an almost unlimited supply of energy, which led to widespread synthesis of nitrogen-based fertilizers and the mechanization of large-scale land clearance for agriculture. These, together with many other innovations in, e.g., sanitation and healthcare, led to an exponential increase in human populations from approximately 1000 million in AD 1800 to over 7000 million by the year AD 2013, and a 50-fold increase in economic production (Steffen et al., 2011). This is age of the Anthropocene.

The Anthropocene's first appearance in print was by Crutzen and Stoermer (2000) "… to emphasize the central role of mankind in geology and ecology by proposing to use the term 'anthropocene' for the current geological epoch." Its novelty, and in part its attraction, is that it describes a period during which modern humans have globally become a significant force of nature, rivaling natural environmental, and geological processes. Intrinsic to the definition are the observations that humans have pushed many of the Earth's systems beyond natural variability. For example, carbon dioxide concentrations (CO_2) in the atmosphere are higher than they have been for millions of years, while human activities (such as agriculture) dominate global nitrogen budgets (Galloway et al., 2004).

Perhaps surprisingly, one of the most contentious aspects related to the concept of the Anthropocene is when it started. For example, did it start with the onset of the Industrial Revolution (e.g., Crutzen and Stoermer, 2000; Steffen et al., 2011), or much earlier in human history with the commencement of Neolithic forest clearance approximately 8000 years ago, followed by the expansion of paddy fields for rice cultivation *c*.5000 years ago (e.g., Ruddiman, 2003, 2013). This is known as the early anthropogenic hypothesis. Attempts to define the start of the Anthropocene are not a trivial task and have implications beyond the nature of recognizing a period of intense human impact. For example, there is a push for the Anthropocene to be designated as a new, formal geological epoch (Zalasiewicz et al., 2011). For several years, an Anthropocene committee has been looking into the implications of such a designation, and if a new designation based on stratigraphy is even possible (Gale and Hoare, 2012). If the Anthropocene was formally ratified, then that would mean we have left the era of the Holocene. Key to this debate is the nature of a stratigraphical golden spike; the golden spike is the transition that marks the end of one geological era and the start of another. The transition is usually characterized by well-defined changes in biological fossils and/or sedimentology, discernible in different regions of the world. Considerable debate has ensued as to defining a golden spike between the Holocene and the Anthropocene, and at the time of writing, there is no resolution. The International Commission on Stratigraphy hopes to make a decision by 2016.

In this article I take the view point that the Anthropocene started with the onset of the Industrial Revolution purely on the basis that the temporal designations suggested by Steffen et al. (2007) provide a good structure for the assessment of human impact on the earth, including Pre-Anthropocene impact; Stage 1: utilization of energy from fossil fuels: AD 1850–1945; and Stage 2: exponential increase in energy consumption and population growth from 1945 – to the near future.

Pre-Anthropocene Impact/Early Anthropogenic Hypothesis

Prehistory

Phylogenetic evidence suggests that the early hominin *Homo erectus* used fire to modify their environment and cook food *c*.1.8 Ma years ago, which influenced her evolution and growth of brain size. Modern humans (*Homo sapiens*) evolved in Africa approximately 0.2 Ma, and undertook diachronous migrations into other continents. It is widely recognized that modern humans played a major role in altering biodiversity and landscapes across continents and islands since at least the past 50 000 years. For example, humans have been implicated in the decline and often extinction of hundreds of large mammalian species (called megafauna) across North and South America, Eurasia, Australia, and many oceanic islands (see Barnosky et al., 2004, for a review). Only in Africa and the oceans have megafauna largely escaped wide-scale extinction, although hundreds of species are currently under severe pressure. However, although humans may have contributed to increased rates of megafauna extinctions (e.g., through hunting and alteration of habitats), climate change is also implicated (Wroe et al., 2013), and when considering

megafauna extinctions worldwide, it seems likely that both climate and anthropogenic activity acted in tandem (Prescott et al., 2012).

Agricultural Revolution

The expansion of domestication and agriculture in multiple regions around the planet (e.g., see Fuller et al., 2011) has had major impacts on landscapes, biodiversity, and atmospheric chemistry since the start of the Holocene. The Neolithic revolution from about 8000 years ago led to large areas of forest being felled and burned to improve agricultural land. Ruddiman (2003) put forward the hypothesis that forest clearance led to an overall increase in atmospheric (CO_2) (**Figure 1(b)**, which has contributed to small but sustained elevated global temperatures (**Figure 1(c)**). Some 3000 years later, agricultural expansion in southeast Asia led to widespread cultivation of rice in paddy fields, and possibly concomitant global increases in global methane (CH_4) concentrations (Ruddiman, 2003; Fuller et al., 2011) (**Figure 1(a)**). Whilst there is still debate about the contribution of these land-use practices toward early Holocene greenhouse gas (GHG) concentrations in the atmosphere, early human alteration of the landscape at broad regional scales is increasingly being recognized (Ellis et al., 2013).

Anthropocene Stage 1

A principal reason why population numbers and energy consumption were kept in check for much of human history was because societies were dependent on rather inefficient mechanisms to provide energy, which relied upon either natural forces (e.g., wind, flowing water) or organic fuels especially wood, peat, and in Europe and China at least, coal over the last millennium. The turning point seems to have been when the Scottish inventor James Watt made improvements to the steam engine at the end of the eighteenth century. This allowed for much more efficient energy generation, which contributed to the start of the Industrial Revolution. For the first time, sufficient energy could be used to chemically generate fertilizers from atmospheric nitrogen, literally getting nutrients from air. This allowed much better agricultural yields to be gained, which together with better medical care, led to

Figure 1 Early anthropogenic hypothesis: (a, b) Preindustrial and industrial-era CH_4 and CO_2 increases from anthropogenic sources. (c) Warming caused by anthropogenic greenhouse gases, with global mean temperature on scale at left and high-latitude temperature on scale at right. From Ruddiman, W.F., 2003. The anthropogenic greenhouse era began thousands of years ago. Climate Change 61, 261–293.

rapidly increasing human populations. Burning of fossil fuels led to increases in atmospheric GHGs, especially CO_2, whilst increasing agricultural practices generally led to increases in CH_4 and nitrous oxide (N_2O) (IPCC, 2007). That these concentration increases are apparent in Antarctic ice cores highlights their global atmospheric distribution.

Increasing fossil fuel combustion and agricultural activities also led to the production of vast quantities of sulfur dioxide (SO_2) and nitrous oxides (NO*x*), which in the atmosphere converts to sulfate (SO_4) and nitrates (NO_3), and leads to acidification of freshwaters and terrestrial ecosystems. Acidification has been especially problematic in regions where catchment geology is base poor, including large parts of northern Europe and North America. Continental scale changes in freshwater diversity were recognized as far back as the early 1980s, and although international legislation was adopted to reduce acidification, biological recovery is being hampered due to climate change (Battarbee et al., 2010).

Anthropocene Stage 2

Post Second World War, global networks of communication and finance were set up to promote greater co-operation between countries. Forty-three countries met at Bretton Woods, New Hampshire, USA, to rebuild the decimated global economy based on neoliberal/capitalist thinking. The conference led to the formation of the International Monetary Fund (and eventually to the World Bank) and open trade agreements. The conference also led to networks of international scientists and engineers leading to major technological advances such as development of nuclear energy and construction of massive structures such as rigs for drilling oil in deep waters. In the early 1960s, subsidies for agriculture were widespread (e.g., the European Union Common Agricultural Policy), which resulted in more intense land use and application of fertilizers. This in turn resulted in widespread nutrient enrichment of freshwater and coastal ecosystems and declines in biodiversity. New oil stores were exploited, concomitant with generation of cheap energy via power stations, which led to very rapid increases in GHG emissions. Factory production of goods were internationalized and made cheap, further integrating global economies.

The rate of societal change, energy consumption, and population growth post Second World War was so dramatic that this period is frequently referred to as the 'Great Acceleration' (Hibbard et al. in Steffen et al., 2007) (**Figure 2**). It is worth noting that energy consumption during this period was driven mainly by countries such the USA, Germany, UK, and France. But in the last decade, new nations are rapidly increasing consumption rates, including Brazil, Russia, India, China, and South Africa, with other countries predicted to become major consumers in the near future (e.g., Nigeria). Impacts on the environment include accelerating increases in GHGs, rapid increases in coastal pollution and exploitation of fisheries, and worrying increases in species extinctions. These impacts stem especially from population increases, energy consumption, and land-use changes.

During this period, scientific endeavors with respect to understanding impacts on the environment have on balance been reactive rather than proactive. For example, realization that acid rain was having transboundary negative impacts in Europe and North America was initially tackled by the UNECE Convention on Long-Range Transboundary Air Pollution (CLRTAP) which was signed in 1979 and entered into force in 1983. The potential danger of artificial greenhouse chlorofluorocarbon gases (CFCs) on ozone in the atmosphere was recognized by Molina and Sherwood in 1974. Observations of the ozone hole across Antarctica in 1985 quickly led to the internationally ratified Montreal Protocol in 1987 which resulted in start of the decline of the manufacturing of CFCs and other ozone-depleting substances. The Montreal Protocol is widely seen as being very successful, to such an extent that the curb on these GHGs may also have acted to protect climate from further warming (Velders et al., 2007).

Case Studies

Atmosphere

Some of the most dramatic human impacts on the Earth linked to the Anthropocene are related to increases in GHGs, especially CO_2, CH_4, and N_2O. Although the latter two have greater greenhouse potencies with respect to CO_2, because CO_2 is much more abundant, it has the highest global radiative forcing (e.g., approximately 1.66 W m^{-2} in 2005; IPCC, 2007). Increased concentrations of atmospheric CO_2 are mainly from combustion of fossil fuels (*c*.74%), although land-use change, such as deforestation, is a small (*c*.22%), but important component. The oceans and terrestrial biosphere both play an important role in regulating atmospheric CO_2 concentrations, and since the 1980s have removed approximately half of anthropogenic emissions (IPCC, 2007). In recent years annual CO_2 emissions into the atmosphere have surpassed 30 billion tonnes, leading to CO_2 levels surpassing 400 ppm at Mauna Loa Laboratory for the first time in 2013. This far exceeds preindustrial values of *c*.280 ppm, and now far exceeds natural variability of atmospheric CO_2 over the past few million years (Monastersky, 2013), long before the arrival of modern humans onto the Earth.

Recent increases in atmospheric concentrations of methane are also ascribed to human activities including exploitation of fossil fuels and agricultural practices. Methane is about 20 times more potent a GHG than CO_2, and current levels in the atmosphere reached over 1800 ppb in 2011, and far surpass natural variability over the past 650 000 years (320–790 ppb; IPCC, 2007). The third important GHG is N_2O, and although approximately two-thirds of this gas derives from natural sources, excess emissions caused by agricultural activities have resulted in 2011 values of 324 ppm in comparison to preindustrial values of *c*.270 ppm (IPCC, 2007).

Why are these increases important? Globally, increased GHGs from anthropogenic activities has resulted in unequivocal warming of the climate system (IPCC, 2007), including both atmosphere and oceans. Impacts on the oceans, cryosphere and terrestrial biosphere are wide ranging with varying degrees of understanding. For example, increased atmospheric temperatures have resulted in nine of the hottest years ever recorded since 2000 (with the exception of 1998). The oceans

Figure 2 (a) The increasing rates of change in human activity since the beginning of the Industrial Revolution. Significant increases in rates of change occur around the 1950s in each case and illustrate how the past 50 years have been a period of dramatic and unprecedented change in human history. (b) Global scale changes in the Earth System as a result of the dramatic increase in human activity: (i) atmospheric CO_2 concentration; (ii) atmospheric N_2O concentration; (iii) atmospheric CH_4 concentration; (iv) percentage total column ozone loss over Antarctica, using the average annual total column ozone, 330, as a base; (v) Northern Hemisphere average surface temperature anomalies; (vi) natural disasters after 1900 resulting in more than 10 people killed or more than 100 people affected; (vii) percentage of global fisheries either fully exploited, overfished or collapsed; (viii) annual shrimp production as a proxy for coastal zone alteration; (ix) model calculated partitioning of the human-induced nitrogen perturbation fluxes in the global coastal margin for the period since 1850; (x) loss of tropical rainforest and woodland, as estimated for tropical Africa, Latin America, and South and Southeast Asia; (xi) amount of land converted to pasture and cropland; and (xii) mathematically calculated rate of extinction. Reproduced from Steffen, W., Grineald, J., Crutzen, P., McNeill, J., 2011. The anthropocene: conceptual and historical perspectives. Philosophical Transactions of the Royal Society A 369, 842–867.

have also been warming up, and actually absorb over 80% of extra heat produced by higher GHGs (Tyrrell, 2011). Increased warming has also resulted in glacier retreat around the world and decline in Arctic sea-ice cover. Both melting ice and ocean expansion through increased heat have resulted in rapid increases in eustatic sea levels.

Ocean Acidification

The oceans play a crucial role in regulating atmospheric CO_2 because they absorb up to one-third of CO_2 emitted every year through pollution and deforestation. Since the start of the Industrial Revolution, increasing global atmospheric CO_2 concentrations have major impacts on ocean biogeochemistry, which is highly likely to have major consequences for marine biodiversity in the future. When CO_2 dissolves in sea water, it forms carbonic acid which acts to naturally increase the acidity of sea water. Since the start of Anthropocene stage 1, the pH or surface waters of the ocean has dropped by 0.1 pH unit, to pH 8.1. This may not sound a lot, but in fact the rate of acidity increase is over an order of magnitude faster than has occurred for millions of years (Doney et al., 2009), and if CO_2 emissions are not curbed, then ocean acidity may fall by a further 0.3–0.4 units (Schiermeier, 2011).

Figure 2 (*continued*).

Why is ocean acidification important? Many organisms that live in the sea, from plankton to oysters to corals, use calcium carbonate ($CaCO_3$) to build their shells and skeletons. However, increased dissolved CO_2 in marine water combines with carbonate ions (to form bicarbonate), which means that $CaCO_3$ can no longer be used. Furthermore, if the concentration of carbonate declines to low enough levels, shells and skeletons weaken and may start to dissolve. For example, coral reefs are seriously under threat from ocean acidification, as highlighted by several laboratory studies which demonstrated a decline in calcification rates related to acidification (Doney et al., 2009). However, with increasing observations in the field, impacts from acidification are not as straightforward as early studies suggested, with apparent greater spatial and temporal heterogeneity (e.g., Pandolfi et al., 2011).

Biodiversity and Land-Use Change

Biological diversity (biodiversity) helps to maintain healthy ecosystems, e.g., water quality, primary production, and decomposition. Biodiversity is therefore an important component of ecosystem services, which contribute to healthy, human livelihoods. Increasing biodiversity results in increased ecosystem stability (Cardinale et al., 2012). Conversely, declines in biodiversity can have major implications for ecosystem functioning and the services that they provide, with complex outcomes. For example, local species losses can have as significant an impact on, e.g., local primary production as effects from global drivers such as climate change (Hooper et al., 2012). However, in a meta-analysis of over 100 studies the introduction of new species resulted in increases in primary production and other ecosystem services, despite declines in richness of native species (Vila et al., 2011).

Anthropogenic activity during the Anthropocene may be driving the planet to a 'modern extinction crisis' because extinction rates are orders of magnitude greater than background rates (Barnosky et al., 2011). Drivers of species loss are varied, and include direct hunting, habitat change and fragmentation, competition for resources, pollution, and anthropogenic global warming, on top of natural factors such as climate change.

However, it is far from clear whether biological change, including declines in biodiversity and land-use change, will lead to a planetary-scale state shift in the Earth's biosphere (Barnosky et al., 2012; Rockstrom et al., 2009). At local and regional scales, species losses are often compensated for by species introductions and invasions (Ellis et al., 2012). This is important as ecosystem functioning at local and regional scales is dependent on species maintaining high levels of biodiversity. Brook et al. (2013) further challenge the concept that the terrestrial biosphere has a planetary tipping point as responses to anthropogenic change are likely to be heterogeneous in time and space, limiting the usefulness of any single aggregate such as global species richness.

Conclusions

The Anthropocene epoch is increasingly recognized as a paradigm shift in global environmental change research. Since the beginning of the Industrial Revolution, human activities have played an ever-increasing role in the functioning of the Earth System. Although global climate has emerged from the end of the Little Ice Age into the early stages of global warming, many of the dramatic environmental and ecological changes that have occurred since the early nineteenth century owe their origins to technological advances leading to unconstrained use of fossil fuels, increased supply of energy and rapid population growth, and rapidly increasing production and consumption of goods and services. We now live in a no-analog world in which a deeper understanding of the principal environmental, socioeconomic, and cultural transformations of the last three centuries is a vital prerequisite for working toward a viable future for human populations. There is little doubt that humankind will remain a major geological force into the foreseeable future. How Earth System functioning responds will be dependent upon key societal and technological decisions made now and in the near future with respect to, e.g., restructuring of national and international institutions through Earth System governance.

Abstract

This article proceeds by highlighting the key organizing questions that animate the variety of anthropological approaches to education, past and present. With a focus on U.S. contributions to the field of anthropology of education, the article also acknowledges the contributions of other national traditions. With its early roots in studies of cultural transmission and 'culture and personality,' the field has grown to incorporate questions about cultural continuity and change, schools and inequality, and the education of racially minoritized groups. A wide range of interdisciplinary dialogues and advocacy efforts for social justice now characterize anthropological approaches to education.

Anthropology of Education as a Tradition of Inquiry

Most anthropological approaches to education have been developed in the subfield of cultural anthropology known as the anthropology of education. In the United States, this subfield has been institutionalized in one form as the Council on Anthropology of Education, which holds annual meetings in conjunction with the American Anthropological Association and publishes the refereed journal, *Anthropology and Education Quarterly*. However, many other scholars, including those serving as educators, activists, organizers, or consultants outside the academy, may identify themselves as anthropologists of education, if they are principally concerned with the social and cultural dimensions of teaching and learning. We describe the primary questions, concepts, and approaches of the field primarily from the U.S. perspective, while drawing in questions from other vibrant traditions of educational anthropology, such as those of Mexico and Argentina.

Perhaps the best way to articulate anthropological approaches to education is to state the questions that they most urgently pose and attempt to answer. Anthropology as a discipline asks the broad fundamental question, "How and why do human beings behave the way they do?," and it typically pursues the answer to these questions along five analytic dimensions: *historical*, *comparative*, *local*, *holistic*, and *cultural*. Anthropology is first and foremost a historical and comparative discipline. The discipline studies the evolutionary dimension of human existence, the sweeping historical development of human society from early hominid origins to postindustrial globalization. In and through such a historical perspective, anthropology also constructs knowledge about human universals and particulars through systematic comparison of different social groups.

The anthropology of education is firmly rooted in the branches of sociocultural, linguistic, and applied anthropology. Sociocultural anthropology's emphasis on *local* action and local meaning cannot be separated from its methodological preference for long-term participant-observation and ethnographic analysis. Related to this emphasis on local action is an insistence on understanding the context in which such action takes place. Yet even as the local is stressed, anthropology also has long advocated the principle of *holistic* analysis. This means that whatever the particular activity or practice under investigation, it is important to understand how it is interconnected with other dimensions of social life. In other words, nothing can be understood in isolation; each contextualized practice is always part of a larger whole, which ranges from biological and environmental influences to political and economic. Finally, anthropologists typically stress the *cultural* dimension of human society and action. Culture refers to the symbolic meanings that inform any observable social behavior or institution. For anthropologists, all human action is significantly influenced by cultural meanings, practices, and beliefs.

As a subfield of the discipline, then, anthropology of education begins by asking, first and foremost, "How and why do human beings *educate* the way they do?" Within this broad purview, the process of education can be defined as humanity's unique methods of 'teaching and learning' – that is, of *acquiring*, *transmitting*, *producing*, and *transforming* cultural knowledge for interpreting and acting upon the world. Anthropologists of education wish to understand how teaching and learning are organized socially and culturally. Of course, education is much broader than schooling, which is an institution of more recent historical invention. Until the development of agriculture and the rise of city-states some 10 000 years ago, tribal and band societies surely educated their young through complex and deliberate practices, but not in separate institutions like those we call schools. Rather, education was probably a seamless part of everyday life, and took place through the productive and ritual activities characterizing a society's way of life. At least as far back as Margaret Mead's classic 1928 work, *Coming of Age in Samoa*, anthropologists have examined the myriad forms of teaching and learning that comprise everyday social life – ranging from observation and imitation, and guidance and demonstration, to more intentional didactic techniques. Such studies of informal education have led to important findings about the nature of 'situated learning' (or situated cognition) and the 'communities of

practice' through which such learning takes place (Lave and Wenger, 1991).

In contrast to informal education, a school is typically a hierarchical setting, often age-graded, where, as Judith Friedman Hansen (1979) puts it, "learners learn vicariously, in roles and environments defined as distinct from those in which the learning will eventually be applied." Only since the beginnings of the modern period some 200 years ago – a period characterized by the rise of capitalism, large-scale urbanization, the consolidation of the nation-state, and the ubiquity of the printing press – have mass school systems been created, and much of human learning been channeled through schools. And even within schools, it is important to note, teaching and learning is not confined to the hierarchical roles of teacher and student; amongst students themselves, peer-to-peer learning constitutes a good deal of school-based education, too. So the second big question the anthropology of education asks is some variant of, "How exactly does education occur in schools, both within and beyond the classroom, and what relationship does that kind of teaching and learning have to educational processes occurring in many places outside of schools?"

Of course, the more specific questions about schooling and education often have emerged out of the encounter with the specific social and political realities, and the social movements, of the countries where anthropologists have found themselves working. Basic scientific questions have become entwined with political and applied questions. In the United States, for instance, the civil rights movements, racial desegregation, and the growth of ethnic diversity through the 'new immigration' of the 1960s brought forth the need to conceptualize the relationship between ethnic minorities and their schools. Thus, many U.S. anthropologists asked the question, "How do ethnic and racial minority groups organize their education in the community and home, and how do the educational practices of schools contrast or conflict with the educational practices of community and home?" Much work driven by such a question came to be known as the 'cultural difference' or discontinuity approach. By the 1980s, new patterns of immigration in Europe provoked a similar interest in cultural differences and in intercultural communication on that continent. At that time, too, U.S.-based anthropologists of education frequently noted the entrenchment of race, class, and gender divisions in the U.S. society. Though engagement with feminism, neo-Marxist scholarship, Pierre Bourdieu, and critical race theory, anthropologists of education asked questions about power, such as, "How do schools organize teaching and learning in ways that effectively reproduce social structural inequalities, and how do students and their families respond to such practices?" As we shall show further down, anthropologists of education also began to pursue social justice through their work, asking questions that were at least as action-oriented as analytic, such as, "How can teachers and learners be empowered to question and transform their educational circumstances, and how can institutions be designed to facilitate such transformation?"

In Latin America, of course, the questions have varied. Anthropologists of education in Mexico at an early stage drew together and critiqued theory from both the Anglo-American and the French traditions (e.g., 'cultural difference' and 'reproduction'), but soon developed their own concepts and questions. On the one hand, the ongoing denial of school access to millions of impoverished Mexicans prompted the question, "Whom does schooling serve, and why?" On the other hand, the prevalence of dominant assumptions about how schools and teachers worked brought forth the question, "How is the 'everyday life' of the school organized, and in what does 'teachers' knowledge' consist?" This prompted a deeper *historical* anthropological investigation of the roots of local Mexican school structures and cultures, in relation to national reforms and policies. More recently, in the context of contradictory neoliberal education policies and the new discourse of the 'pluralistic' nation, anthropological work has emphasized education in nonformal settings, youth cultures, interculturality, and the educational implications of class and racial–ethnic differences.

In Argentina, meanwhile, questions of diversity and democracy have been foremost. The development of educational anthropology went hand-in-hand with the struggle against military dictatorship and the restoration of democracy in the early 1980s. Argentine anthropologists of education have focused on mechanisms of power and control in schools, as well as class-based discrimination and exclusion. Among the key questions they have asked are, "How does power work in schools, and what is the role of the teacher vis-à-vis the state and the family?" More recently, with the rise in cultural diversity through in-migration from Bolivia and Paraguay, and the growing recognition of Argentina's own indigenous and ethnic minorities, Argentine anthropologists have increasingly asked, "How are cultural differences amongst students negotiated in schools, and how can schools recognize such differences without using them as a basis for exclusion or discrimination?"

In Brazil, anthropologists pursue several questions in concert with sociologists, social psychologists, and other colleagues, including these: "How does racism operate in the lives of teachers and students in the context of a myth of racial democracy? How should we understand youth not simply as victims of poverty and violence but also as strategic actors themselves? How should indigenous peoples' access to mainstream education be supported while respecting indigenous knowledge and pedagogical projects?" (Gomes and Gomes in Anderson-Levitt, 2011).

In Europe, meanwhile, research questions also develop out of local social contexts and disciplinary histories. In Denmark, in the context of the welfare state, many anthropologists and their colleagues in related disciplines focus on the question: "Are children and youth growing up in environments that allow them to grow as moral beings and to gain skills to support themselves and take part in democratic society?" (Anderson, Gulløv and Valentin in Anderson-Levitt, 2011). In Germany, where educational scholars conduct ethnographic studies on a range of topics, one group inspired by philosophical anthropology, by the Annales School of France, and by U.S. cultural anthropology asks: "How do children learn to become social persons through everyday rituals at home and at school?" (Wulf in Anderson-Levitt, 2011). Meanwhile, the new immigration has inspired in Italy, Spain, and other countries studies of children's languages and cultures under the rubric of interculturalism (Gobbo in Anderson-Levitt, 2011), which emphasizes learning across cultures, as opposed to simply

recognizing and problematizing cultural differences, as a multicultural or cultural difference approach is said to do. In Spain, anthropologists of education (Díaz de Rada and Jiménez Sedano, 2011) continue to raise fundamental questions about the ways that bureaucratic school categories propagate harmful assumptions about immigrant students and their families.

Key Concepts

From a broad anthropological perspective, we could say that the educational process in different societies fundamentally oscillates between an emphasis on continuity and an emphasis on change. This is because the challenges of evolution, broadly speaking, are thought to require a social group to adapt to novel circumstances through innovation, and then consolidate and perpetuate this adaptation through repeated inculcation. Education is seen as underwriting every human group's ability to adapt to its environment and thereby reproduce the conditions of its existence. According to Jules Henry (1963), Fred Gearing, George Spindler, and others of their generation, whose roots often lay in village or community-based studies of child socialization, education is, in this sense, a fundamentally conservative social process, only occasionally tinged by innovation. Accordingly, the main research questions are: "What allows a society to adapt to its environment while retaining some historical cohesion and continuity? How does a society conserve essential features of its cultural and technological repertoire?" Early anthropology of education largely sought to address these questions through an analysis of the process of *cultural transmission* – the passing on of basic cultural knowledge and values across the generations.

However, as questions of conflict and power came to the fore in the social sciences, along with the cognitive and linguistic turn, anthropologists of education began to question their functionalist assumptions, and to examine more closely how education contributed to change. "If cultural transmission occurred smoothly, how did societies challenge their own inertia? If education mainly served to mold the young into the cultural patterns of a society, how did innovation ever occur? If children were educated 'traditionally,' how did they respond to sudden and dramatic social change? And in complex, socially stratified societies, how were cultural messages differentially transmitted and received?" In response to such questions, attention turned away from cultural transmission, and the role of 'teachers,' toward *cultural acquisition*, or the role of the 'learner.' "A related emerging question was, how did relatively novice individuals acquire the basic cultural knowledge of a society, and what distinctive personal or categorical interests and traits might they bring to the learning process?" This question spawned a tremendously fruitful collaboration between anthropology and psychology, giving rise to the new field of 'cross-cultural psychology.' The work of the Soviet psychologist L.S. Vygotsky, with its sociohistorical emphasis on *activity* and the role of symbolic 'tools of mediation' in the relation between individual and society, has become central to this field. More recently, as we have mentioned, Jean Lave and Etienne Wenger (1991) have proposed a powerful theory of 'situated learning,' in which society is fundamentally composed of overlapping 'communities of practice' that serve as the vehicles for cultural acquisition.

Hand in hand with the emphasis on cultural acquisition came the increasing recognition of cultural complexity. Rather than a body of 'shared' or common meanings that one could identify with a particular society, culture was reconceived as a pool of symbolic resources, distributed unevenly across societies and social groups, which individuals can negotiate and appropriate with varying degrees of agency (Goodenough, 1976). An important overarching concept that has emerged to encompass the processes of cultural transmission and acquisition is that of *cultural production*. Education may be seen as a constant process of cultural production. Even in those cases where education is oriented primarily to the achievement of continuity, in a relatively closed social system, the theoretical possibility of modification and change always exists. If this is true in small-scale societies, then it must be all the more true in highly stratified, differentiated, and urbanized societies. So new key questions emerge: "In the process of acquiring transmitted cultural knowledge, how can individuals or subcultures modify or extend the knowledge, in effect organizing the knowledge for themselves while producing and adding new knowledge to the common stock? Or how can individuals or subcultures *resist* the transmission of knowledge, and thereby produce their own alternatives?" Indeed, one stream of work analyzes how differing 'models of the educated person,' produced both in and out of school contexts, may clash and conflict with one another (Levinson et al., 1996). For instance, in Doug Foley's (2010[1990]) critical study of a high school in south Texas, *Learning Capitalist Culture*, teachers and administrators seem to collude with mainstream (mostly white) students to produce a model of the smooth-talking, superficially compliant student who knows how to display highly packaged, or 'commodified,' knowledge. Meanwhile, rebellious (mostly Mexican) students, like the *vatos*, come to produce their own alternative model of the truth-talking, worldly-wise educated person, keen to point out the hypocrisy they see around them.

Research Methods and Related Disciplines

In approaching their specific contexts and exploring these questions, anthropologists of education typically employ ethnographic methods. Ethnography relies principally on in-depth participant observation for prolonged periods of time, accompanied by various kinds of interviews (individual, group, focus group, etc.), document analysis, and/or qualitative data prompts (conceptual mapping, open-ended surveying, photo-voice, etc.). Depending on the questions or context, anthropologists of education may also employ in-depth life history interviewing or mixed methods (some quantitative analysis).

Long-term participant observation is an approach also used for nearly a century by some schools of sociology, and also by sociolinguists, social psychologists, and scholars trained specifically in education studies. Thus, a sociology of education using similar research methods and asking similar questions has developed in parallel with educational anthropology. In the United States, sociologists using qualitative methods such as Hugh Mehan, Margaret LeCompte, and Annette Lareau, not

to mention social psychologists like Michelle Fine, or critical education scholars like Gloria Ladson–Billings and Sofia Villenas, have significantly influenced educational anthropology and been influenced by it.

In some countries, such as the United Kingdom and France, sociology of education is the dominant field and ethnographic studies are usually conducted by scholars who identify as sociologists or as education scholars – as in the journal *Ethnography and Education* or in the qualitative studies published in *Éducation et Sociétés*. While their research methods and the analysis of inequality tend to parallel educational anthropology's, the sociologists are more likely to focus on social class and, at least in France, less likely to turn their attention to race or ethnicity. In addition, sociologists of education generally study education 'at home,' whereas for reasons of history and structural dominance, some anthropologists in the United States, as well as in many wealthy Northern countries (e.g., Denmark, the UK, Japan), have conducted their studies 'abroad,' outside the country of their birth or training.

Until recently, anthropologists of education typically spent many months observing and interviewing people at a particular site (a community, a school, even a particular classroom), in order to develop a deep and nuanced understanding of the social and cultural dynamics of the context. More recently, anthropologists of education have extended the ethnographic method to multiple sites and contexts, in an effort to understand how signs and social forces circulate through and across many different contexts (e.g., Nespor, 1997), or how cross-cultural and cross-national contexts can be empirically compared (Anderson-Levitt, 2002; Tobin et al., 2009). Relatedly, a burgeoning anthropology of education policy and reform has yielded methodological models for studying processes and discourses across ethnographic sites and levels of social scale (Vavrus and Bartlett, 2009; Rosen, 2009; Koyama, 2010).

Directions and Trends in the U.S. Anthropology of Education

Concepts from critical social theory and a growing sense of urgency about the damage done by educational inequality have informed the field's growing commitment to social justice. Once anthropologists of education came to conceive of the complexity and full range of education as a dynamic and contested process of cultural production, this allowed for a link to *theories of schooling for social reproduction and for liberation*. As we have seen, in the late 1960s and early 1970s U.S. anthropologists of education tried to address persistent racial inequalities in educational achievement. One of the prevailing popular explanations for such inequality was that ethnic minority students were 'culturally deprived' in relation to their White counterparts, and therefore needed a kind of cultural remediation. This came to be known as the 'deficit' approach to educational achievement. Anthropologists quickly countered that it was not a matter of cultural deprivation, but rather of cultural *difference*. They argued that ethnic minority students tended to do more poorly in school because their cultures of origin used different epistemologies, styles of communication, and participant structures to educate children in the home. Such cultural attributes, they argued, differed sharply from the mainstream, middle-class cultural rules governing school life.

The Nigerian-born immigrant John Ogbu developed a critique of this reigning 'cultural difference approach.' He argued that anthropologists needed to take into account the 'cultural ecology' of a group's response to schooling. Making an important distinction between so-called 'voluntary' or immigrant minorities, and so-called 'involuntary' or castelike minorities (who typically had become part of a society through conquest), Ogbu (2008) showed that the question of school achievement could not be separated from the history of a group's structural position in society, and the repertoire of attitudes and practices that had developed out of that position. Involuntary minorities, such as African-Americans in the United States, had developed alternative and 'oppositional' cultural forms and strategies – what Ogbu called secondary cultural characteristics. Their problems with school could not be reduced to mere differences in primary culture or linguistic style. The problems were more deeply rooted in the history of subordination and its consequences.

Both Ogbu and the cultural difference anthropologists accepted the liberal premises of schooling, and they believed in the positive opportunities for social mobility that increased school achievement might provide. Yet by the middle of the 1980s, newer work in the sociology of education (e.g., Paul Willis, Pierre Bourdieu) and social theories of power helped anthropology focus a more critical lens on schools. This might explain why some anthropologists and educators would criticize John Ogbu for tending to place the burden of school performance on the involuntary minority families and students themselves. Now more than ever, schools were seen to serve dominant interests in the social reproduction of inequality, even as anthropologists also explored the paradoxical potential of schools as contexts to produce knowledge that might liberate individuals and groups from systems of domination.

For example, in a major work that culminates many years of fruitful collaboration, Hervé Varenne and Ray McDermott (1999) show how 'failure' is deeply and inexorably embedded in the U.S. school system through linguistic categories and interactional repertoires. This work also illustrates how the field has been enriched by important advances in the ethnography of communication and the ethnomethodological approach, which originally developed out of phenomenological sociology. Meanwhile, other work has taken up the basic insights of the cultural difference approach and the critique that John Ogbu made. Taking seriously the influence of historical experience and racial categories, new work has nonetheless tried to nuance or challenge Ogbu's formulations by looking more closely at institutional (school-level) effects and nondominant students' varying personal histories (Davidson, 1996; Fordham, 1996; Mehan et al., 1996).

Anthropologists have also worked alongside sociolinguists to challenge rigid, school-based definitions of literacy by documenting the many different ways that people use written texts, from grocery lists to love letters to political petitions seeking redress. Their work particularly underlines the functions of multiple literacies in multilingual societies, arguing against the presumption that what counts as literacy is academic proficiency in a dominant, often colonial language (Collins, 1989; Lee, 2007; Street, 1993). Other scholars of literacy, like Mexican

Elsie Rockwell and the French scholar Anne-Marie Chartier, place in deep historical and cultural context the formal instruction of literacy in schools, showing, among other things, how print materials are always mediated by teachers' verbal practices. Meanwhile, studies of multilingual and multimodal literacy practices within transnational social fields have explored the identities, relationships, and social networks that undergird concepts of transnational literacies. Transnational literacy studies explore language and literacy practices that transmigrants develop across geographical borders and emphasize the always situated, contextual, and ideological nature of reading and writing (Lam and Warriner, 2012).

In the United States, at least, many educational anthropologists teach in Schools of Education. Their work often and necessarily involves teacher training. At the same time, educational anthropologists have steadily undergone a process of self-critique which has led to increases in collaborative research design and the democratization of research relationships. Both of these trends partly explain the emergence and strength of school-based applied and action research, especially oriented to the empowerment of racially minoritized groups. As noted earlier, a common question in the field now is, "How can teachers and learners be empowered to question and transform their educational circumstances, and how can institutions be designed to facilitate such transformation?" Examples of such work across a range of contexts include Hugh Mehan (2012) and colleagues' attempts to study the consequences of a program to provide special support and mentoring to nondominant high school students, González et al. (2005) work on connecting students' 'funds of knowledge' with school curriculum, and Wyman et al. (2013) work on the ways that Indigenous youth often yearn to speak endangered Indigenous languages, regrouping resources from linguistic and cultural heritages while integrating wide-ranging symbolic resources from broader, dynamic worlds to build on local strengths in the face of language shift, endangerment, and inequities in schooling and society. Much of this work has been conducted by a new generation of scholars who are relative 'insiders' to the communities they choose to study, and thus challenge many of anthropology's traditional epistemological assumptions about the value of an 'outsider' perspective (Foley et al., 2001). Such scholars negotiate new 'decolonizing' methodological stances that involve community members throughout the research process with new youth studies approaches that foreground youth as important cultural actors in their own right (e.g., Cammarota, 2008; Lamont Hill, 2009; Urrieta, 2009).

Another trend in the field is the engagement with globalization processes as constituted by global flows of people, capital, and ideologies. These flows are seen to be in constant contact, simultaneously merging and diverging, and anthropological studies of education have embraced notions of continuous change and transformation. 'Multiple' subjects and 'multiple' cultures bear out the effects of globalization, fragmentation, and hybridity. Thus students, especially children of immigration, diaspora, and transnationalism, are increasingly represented as syncretizers, selecting and hybridizing cultural practices from multiple discursive fields. Within globalization processes, anthropologists of education have shown even greater concern with the "interrelationships among power, knowledge and identity" (Hall, 1999: p.123). Thus, along with cultural production, we may now speak of processes of *transculturation*, *interculturality*, and *transnational flows*, in which cultural knowledge becomes complexly combined and reformulated within both individual and collective repertoires.

A Concluding Note

As we have made clear, anthropologists of education have an interdisciplinary interest in education broadly defined, and with the many ways that teaching and learning has happened historically and culturally, and will continue to happen. Thus, they connect intellectually with historians and sociologists of education on the one hand, and with action researchers and reformers who seek to conceive of schooling and education more broadly outside the current historical constraints on the other. Indeed, many anthropologists of education have attempted to blur artificial binaries between scholarship and advocacy. Anthropologists of education have found that the margins between disciplines can be a space-where authorizing paradigms are breached and often displaced. As the field of anthropology as a whole has positioned itself as an 'engaged anthropology,' and anthropologists as social critics, it is worthwhile to note that the subfield of anthropology and education always has had deep historical roots in engagement, policy, and praxis. The confluence of advocacy anthropology and educational policy continues to be a space for the interrogation of inequities both in and out of schools.

Abstract

Anthropology's relationship to ethics in research has been driven by periodic disciplinary controversies, often in close association with the involvement of anthropologists in successive war efforts, primarily in the U.S. Over time disciplinary ethics have increasingly focused on the unique exigencies of ethnography, as a disciplinary-specific method. While professional anthropological organizations developed codes of ethics beginning in the Vietnam era, historically, disciplinary ethical language has been used in two ways: as a basis for internal disciplinary self-policing and as a means to claim public professional standing as a social science. These uses continue to be prevalent today. But anthropology's relationship to its ethics also has been historically dynamic, changing with changes in disciplinary identity, values, and priorities. Less recognized are the ways that disciplinary ethics have been regularly reconstituted in close proximity to the frontiers of the identity of anthropology as a changing project. Anthropology's ethics reflect the discipline's specific history and identity debates, and they are one key index of these changing frontiers. This is most evident with respect to anthropology's ambivalent relationship to: science, the nation-state, and encompassing normative structures.

One sign of the increasing 'primacy of the ethical,' to borrow from Nancy Scheper-Hughes (1995), is the extent to which anthropology is inclined to regularly revisit and to revise its own ethics standards, usually in reaction to perceived ethical crises. If historically these crises have been precipitated by the involvement of anthropologists in different war efforts, over the years they include other cases where the discipline has left the academy. These crises have seemed to come more often of late, and are more regularly revisited, with anthropologists frequently electing to bring the language of ethics to bear when raising questions about the scope and limits of disciplinary practice. As has been often noted, the use of the discourse of ethics accompanies accusations about breaches of professional conduct in the mode of inward- and outward-looking disciplinary self-policing.

'Ethics' increasingly inform or subsume disciplinary debate about researchers' relationships to counterparts. But ethics in the mode of self-policing is only one sign of what has been a broader turn to critical examinations of ethical, moral, and normative structures and agencies. Anthropology's relation to ethics has become more expansive, informing new research on audit cultures, identity, personhood, the state, rights, advocacy, and relationships of the local to the global. This more expansive relationship still includes a concern for the ethics of anthropology, that is, the set of normative principles understood to govern moral, right or acceptable professional conduct. But it is also informed by the notable growth of an emerging anthropology of ethics, which takes 'ethics' as a subject of ethnographic projects. As Faubion (2011) explains it, such research comparatively pursues the 'becoming and maintenance of the ethical subject.' The fruitful traffic between these two forms of ethical engagement currently informs the growing presence of ethics as a part of the disciplinary landscape.

Ethics and Anthropological Science Wars

During the first decades of the twentieth century, when Franz Boas was busy promoting his eventually triumphant historical particularist vision for cultural anthropology at Columbia University, he also provoked the discipline's first ethics controversy in 1919 with his published assertion that during WWI certain American anthropologists 'prostituted science' by using disciplinary activities as a cover for government-sponsored espionage. Much can be said about this event. But of interest here is that the force of Boas's claim of an ethical breach depends, in turn, upon his strong appeal to the integrity of 'science,' as a clearly demarcated professional vocation which – Boas wanted to be clear – should definitely include a then nascent and actively professionalizing *science of anthropology*.

As ongoing debate about the extent and kind of anthropology's involvement in the activities of the national security state continues to make clear, disciplinary invocations of ethics are a particularly public mode of professional self-policing. But Boas's appeal to science also expressed his specific time and place, articulating a specific professional version of anthropology, which has undergone multiple transformations since. The *science of anthropology* Boas defended in his outraged letter to *The Nation* did not begin with 'value judgments.' Nor should scientists, 'in the service of truth,' involve themselves in 'political affairs.' In broad terms, Boas's anthropology was outside of government and in academic departments, objective, empirically driven, nonnormative, but also skeptical of classification and of a science of culture formulated as generalizable laws.

If an example of the self-reflexive use of ethics to claim professional high ground – a usage still prevalent today – Boas's claims for an anthropological science here suppressed several well-known and founding ambiguities of his project for a newly professional anthropology, many of which are on clear display in his 1887 essay on 'The Study of Geography.' To *The Nation* he strategically foregrounded the scientific over the humanistic, his training in physics over his interest in history, and the naturalist over what he called the cosmographer. At this key professionalizing moment, and even as his understanding of science was considerably more nuanced, Boas at least publicly aligned the ethics of anthropology with an empirically rigorous objective evidence-based model of science consistent with the positivist natural sciences of the day.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12190-7

We can compare the ethical crisis provoked by Boas's (1919) letter to a current controversy involving another eminent anthropologist, Marshall Sahlins. Sahlins resigned in 2013 from the National Academy of Sciences to publicly protest the election of Napoleon Chagnon. The latter's widely cited conclusions about human evolution, genetic selection, and the role of violence among the Yanomami of Venezuela and Brazil, have been highly controversial among anthropologists. And according to Sahlins and others, Chagnon's ethics in the field have also been suspect. Sahlins has described Chagnon's methods as a case of 'research and destroy,' a description linking Sahlins's objections to his other concern, the militarization of the social sciences.

The cases of Boas and Sahlins are notably similar. Over their careers, each has influentially represented the discipline as a 'discipline' among peers and beyond. Both voiced uncompromising disagreement with any anthropological involvement with the U.S. national security state. Both have regularly promoted cultural explanations to discredit the biologically rooted pseudosciences of their respective eras (for Boas, eugenics and racialist evolutionary thinking; for Sahlins, sociobiology). When engaged in debate, both variously emphasized the primacy of empirical findings as an answer to bad science or bad theory. And, of course, both took colleagues publicly to task for violating perceived disciplinary ethical standards, leading to their resignations from the National Research Council.

But these similarities conceal equally notable differences between the two, most evidently, the ways they connect the discipline of anthropology to different notions of science (and of history), and as these connections lend force to their ethical claims. Sahlins connects Chagnon's poor ethics, specifically, his apparent failure to obtain 'informed consent' from Yanomami research subjects, to sociobiology's 'theoretical and empirical underpinnings,' succinctly, the selfish-gene Darwinism of Richard Dawkins and ilk with which Chagnon's work is engaged. And sociobiology fits with a hypothesis-testing 'natural science sense of anthropology' preferred by the National Academies, as opposed to Sahlins's empirically grounded historical explanations of cultural determination. Chagnon's defenders, in turn, regularly depict Sahlins's criticisms as 'antiscientific.'

Most tellingly, Sahlins draws a direct connection between Chagnon-type sociobiology and the military-funded research projects of the National Research Council. In his words, both traffic in the same Western ideology of the 'innate character of mankind,' and aspire to 'making the world safe for self-interest.' For Sahlins, Chagnon's work is an egregious illustration of the 'confusion of capitalist greed and human nature.' Here Sahlins reveals a very different set of commitments to those of Boas, indeed, an ideological axe. Sahlins is making a value judgment, while using professional ethics to defend a moral position about scientific practice as it is connected to competing cultural conceptions of personhood and identity, a judgment which he understands to be part and parcel of the ethical practice of anthropology.

Unsurprisingly anthropology has changed dramatically over the course of the intervening years between the ethical crises provoked by Boas and Sahlins, changes which cannot be summarized here. But Sahlins's objections should be taken in a context of the changing expectations about ethnography specifically, and anthropology generally, as a kind of project. If Boas's ethics were focused on purging ideology (specifically, nationalism) from professionalism, the force of Sahlins's objections assumes the greater ethical urgency invested in the politics of ethnography, with a concomitant greater emphasis on 'informed consent' and 'do no harm' than in Boas's time. His ethical accusations express a change in the ways ethics are used now: less about what is defensibly professionally 'scientific' (as with Boas) and more about the circumstances of ethnographic relationships, where the work of ethnography is often also understood to include previously extraethnographic responsibilities to the values and priorities of counterparts in the field.

Despite the fact that the discipline, in its diversity, has equivocated about the ethics of advocacy for some time, AAA leaders carefully parsed this most recent iteration of the Sahlins–Chagnon debate, responding that both advocacy and science are 'at the core of our discipline.' They go on to explain, "Advocacy suggests at minimum an ethical position to try to protect and better the lives of individuals." The mode of science conversant with this is one recognizing science as a practice 'undertaken in a social context.' This is a far cry from Boas's value-neutral empirical *science of anthropology*. Sahlins's ethics appeal more to what Boas identified as 'humanistic,' and as preferable to an anthropological science modeled on the physical sciences. His updated humanistic anthropology is also equated with more politically-engaged disciplinary practice. This shift is, at once, an expression of the discipline's ethical history and has implications for the contemporary meaning of professional ethics.

Boas and Sahlins, both, address alignments of causality and explanation among biology, history, and culture. Both demote biology while elevating culture. Both labor to describe empirically-informed historical explanations for cultural agency. Where they most obviously differ is in the identification of a properly scientific anthropology. The frontier of this difference has been a fault line of anthropological struggle for self-identification since its inception. The ethical turn of each directly troubles this frontier, which Boas originally conceived in the terms of physicist and cosmographer. Almost a century later, this frontier had shifted to the tensions between ethnography and advocacy. Even in cases of self-policing focused on delimiting professional conduct, ethics are also a dynamic catalyst for theory-building, in this case, for right relations among biology, history, and culture. Navigating what Zigon (2007) describes as moments of 'moral breakdown,' successive ethical turns have also productively defined changing positions along the movable frontiers of anthropological science. When it comes to the contentious relationship of anthropology to science, ethics do productive work.

Ethical Genealogies and Normativity

We now have various historical overviews of anthropology's ongoing, changing, relationship to ethics (see Fluehr-Lobban, 2003; Whiteford and Trotter, 2008), which I will not aspire to summarize here. Boas and Sahlins have their parts. But I do want to emphasize implications of the fact that this has

been a dynamically changing relationship. While not in any way an exhaustive account, Murray Wax (1987) charts disciplinary shifts in ethical attention as closely related to successive engagements with, and attitudes about, the U.S. nation-state. He begins with the WWI era, citing Boas's drive for a *science of anthropology* with 'an ethical calling above the petty rivalries of nationalism.' Between the wars, the discipline became more engaged with challenges of relativism and description of the 'varieties of ethical systems.' During WWII, Wax tells us, ethics became more associated with defense of the 'free world.' After WWII they came to align with a refusal to be employed by national agencies. During the Vietnam era, this coalesced into a more focused rejection of any dealings with the military – a still very active disciplinary discussion today.

I am less concerned with whether Wax's account is accurate – it has been debated – and more interested in Wax's observation that anthropology's ambivalent and evolving relationship to the nation-state, including the machinery, agencies, logics, and interests of the state, is one disciplinary ethical frontier. This ambivalence is of course brightly written into the often fraught history of anthropology's relationship to colonialism and other exercises of state power, a long story that cannot be briefly told. But a postcolonial anthropology has been preoccupied with the effects of agencies of state power upon marginal populations, including the regulatory logics of the state. As the ongoing fruitfulness of concepts like Foucault's 'biopower' or 'governmentality' attest, the exercise of state power upon local worlds continues to be a major disciplinary focus even as it remains a source of ethical discontent.

But the fact that, as Wax notes, disciplinary ethical relationships to the state have been anything but static points to the limits of ethics when conceived as a codified body of abstract knowledge and as an extradisciplinary or universalizing language of self-policing. Nevertheless, when the Code of Ethics of the American Anthropological Association (AAA) has in recent years been used as a lexicon for criticism and sanction of wayward practitioners, this is often with the strategic fiction of ethics as if self-evident, transhistorical, legalistic, prescriptive, regulatory, and as effectively bounding the discipline's professional conduct at any given moment and over time. The dynamic genealogical composition of the discipline's relationship to ethics is ignored and, with it, the productivity of ongoing ethical debate.

The categorical evocation of ethics is at odds with where an emerging anthropology of ethics seems to be heading, suggesting that the discipline's self-reflexive understanding of its practice to its theory production requires more attention. A notable part of this picture is anthropology's increasing rapprochement with the normative after decades of deep suspicion about the totalizing or universalizing claims of normative frameworks. This is a story of several converging genealogies of contemporary anthropological concerns, of which I will point to just a few to highlight anthropology's expanding ethnographic engagement with normative structures.

One genealogical thread has been the discipline's response to the evolving federal oversight of scientific work in the U.S. beginning in the 1970s – itself an expression of the discipline's entanglement with the state. During this period many ethnographers shifted attention from stateless societies to an anthropology in and of the state. In this earlier context of shifting priorities, medical anthropologists – with one foot in the practicing world – engineered a version of 'studying up,' as among the first to take up ethics as an explicit subject of disciplinary research in their own right. In this context, anthropology's emergent critique of bioethics was catalyzed by the development and subsequent regulatory influence of the Belmont Report in the U.S. in 1979, which provided the framework to establish federal standards for the ethics of human subjects protection.

The Report characterizes human subjects as autonomous agents who can exercise individual choice, to the ends of seeking to maximize benefits and to minimize risks. In the broadest terms, medical anthropologists took bioethics, as an abstract framework, to task for disregarding the relevance of social contexts for medical ethical decision-making, while uncritically incorporating a rational choice model of decision-making that assumes the primacy of individual choice. In contrast to bioethicists, these medical anthropologists emphasized the need for a culturally informed understanding of choice, personhood, or 'wellness,' as these vary across different local social worlds, and as caught up in and apprehending the biomedical regimes of modern medical practice in the U.S. and elsewhere.

Several anthropologists have now told the story of the emergence of professional scientific institutional review boards (IRBs), with their priorities framed by the Report's conclusions and the methods of biomedical research, and how this was at best an awkward fit for participant-observation ethnography. But one effect of this emergent federal framework was to further focus anthropological ethics upon the particularities of interaction between fieldworker and hosts, or ethnographers and their counterparts. Whiteford and Trotter's (2008) recent discussion of common problems in anthropological ethics registers this ethnographic slant, given its systematic attention to privacy, rights, harm, justice, advocacy, deception, coercion, voluntary participation, confidentiality, and informed consent. Recent discussions by anthropologists of IRBs continue to dwell on the various questions relating to informed consent, all bracketed by the problem of power in research relationships.

Established critiques developed by Arthur Kleinman (1995) and other medical anthropologists of the medical regime of bioethics – as a regulatory and normative expression of state authority – are an early precedent for the discipline's attention to encompassing normative frames and an example of the ways ethics have become a subject of research. One outcome of this engagement between medical anthropologists and bioethics has been the disciplinary rejection of radical or naïve ethical relativism, as untenable, and as corresponding to a now outmoded and value-neutral comparative exercise among cultures treated as if self-contained distinct worlds. In other words, disciplinary ethics – as with the case of its critical response to bioethics – have made more room for critical engagements with encompassing normativities as these often translate the local agency of the state, other trans-local or global agencies.

The questions of informed consent and prohibition to do no harm, which form the center of anthropology's professional ethics, acquired their current meaningful force in large part in the context of the discipline's grappling with bioethics, as it was then coming to be the prevailing regulatory and normative frame for federally-funded scientific research (including social

sciences like anthropology), and as this gained momentum in the 1970s. Practicing medical anthropologists initiated regular critical dialogue between disciplinary ethical conceptions and bioethics, given their status as a cornerstone of the extra-disciplinary landscape of science ethics, and as one expression of the logic of state power. In the process, anthropology's own ethical conversation has become more sharply defined by its particular disciplinary history and the ethnographic encounter, as, in the words of Rena Lederman (2013), about a specific 'culture of research.'

An Anthropology of Values

Anthropology has been called a 'reformer's science.' It would not be inaccurate to describe anthropology's early professional development as the pursuit of an ethnographically informed social science of comparative ethics. But such a pursuit was pervasive and not foregrounded, instead implicit in what was then understood to be a comparative science of religion, government, politics or culture. This has been suggested as a reason for the relative lateness on the part of the discipline's professional organizations to address ethical oversight as a professional responsibility. The AAA, for example, only adopted a formal position on ethics in 1967 and an ethics code in 1971, since modified multiple times (most recently in 2012).

In parallel and recently, attention has been given to developing a comparative anthropology of morality. This impetus is intended to rectify the deficiency that, in Laidlaw's (2002: 311) words, "Our discipline has not developed a body of theoretical reflection on the nature of ethics." In the context of these discussions, different arguments have been advanced about why this has been the case. One of these has highlighted anthropology's debt to Durkheim, identifying a tendency to equate the moral with the social. As Joel Robbins (2012) has explained, "Because Durkheim defined all properly social action as ethical, anthropologists could assume that everything they studied was ethical, and thus that issues of ethics needed no special attention of their own." Durkheim's legacy, in short, confined the consideration of ethics to the moral lockstep of mechanical solidarity.

A second, more specifically American, account identifies a lack of sustained attention to ethics as a Boasian legacy. A brief recapitulation of this argument, as rehearsed by Mark Goodale (2006), goes like this: since U.S. anthropology came to be synonymous with so-called cultural relativism, and since cultural relativism was typically equated with the categorical rejection of all universalizing normative frameworks (e.g., 'universal human rights'), ethics never evolved into a specific topic of consideration. The 1947 American Anthropological Association's Statement on Human Rights is often exhibit A in this account. A stance of relativistic neutrality and insistence on the comparative moral and political equality of human cultures effectively paralyzed the discipline's methodological and theoretical ability to address normative questions.

Whether anthropology historically has in fact been insufficiently cognizant of the moral life of societies is debatable, but current lively discussion of both the Durkheimian and Boasian reasons for the apparent historical neglect of ethics is in fact one sign of the growing attention to ethics in both ways: as a regulatory discourse of disciplinary conduct and as a subject of research programs. Michael Brown's articulation of an updated 'cultural relativism 2.0' illustrates this turn. In Brown's hands anthropology is a discipline constructively situated to engage the traffic between the 'values' of specific societies and the larger scale moral communities in which they are embedded. Revealingly, Brown (2008: 372) defines cultural systems as themselves "morally charged fields of action and meaning." Cultures, in other words, are significant because they organize specific moral commitments.

Brown's updated discussion of relativism notably makes room for an anthropology that is also regularly concerned with normative frameworks, if primarily at the conjuncture of the global with the local. The discipline's engagement with the normative is part of an ethical turn, and relatively new. The AAA's 1999 Statement on Anthropology and Human Rights, for example, represents an about-face from its 1947 relativist position. If resisting conceptions of the normative as a totalizing system of rationalized abstractions distilled into sets of codes or rules, the 1999 Statement nevertheless establishes an 'ethical commitment' on the discipline's part to recognize and enable 'the human capacity for culture,' defined as a human right. The 1999 Statement stakes out a specifically anthropological vernacular with regard to human rights that at least partially recasts the AAA as an international human rights NGO. Goodale has called this the 'normativization of culture through rights discourses as a political strategy.'

In recent decades, ethnographic research, most obviously with indigenous peoples, has also often incorporated an advocacy role, with anthropologists critiquing, in negotiation with, and leveraging national or international normative precedents on behalf of, and in concert with, indigenous groups increasingly inclined to treat 'human rights' as a part of their own legal arsenal in ongoing transactions to extract resources or recognition from recalcitrant states. With bioethics, this composes part of the ethical frontier of anthropology's postcolonial critique of the agency of the nation-state. Advocacy, treated as an extension of ethnography, encourages normative judgments to be made about particular cultural practices or prevailing global norms while also strategically promoting instrumental uses of normative orders to achieve political goals with counterparts. This orientation to ethics is consistent with what Goodale calls an 'ecumenical anthropology,' that is, an ethically committed ethnographically grounded criticality with respect to normative projects. It is also characterized by the return of values talk in disciplinary discourse.

Anthropological values talk has several sources. The effort to animate a comparative moral anthropology is one of them, concerned as it is with 'cultural values' defined as 'cultural conceptions of the good or desirable.' If resisting any view of morality as a totalizing system, in this emerging research the assignation of values situationally hierarchizes priorities in ways helping to define what counts as moral action. David Graeber's (2001) anthropological 'theory of value' offered as a counter to the neoliberal vision of people as calculating maximizers, draws on anthropological discussions of language, exchange, wealth, and desire, to develop an appreciation of value as a model for human 'meaning-making,' comparatively connecting symbolic systems to the work of defining what is important as a moral project.

These several renovations of value talk have departed entirely from the Boasian suspension of 'value judgments,' reinserting politics, hierarchy, and normative structures back into considerations of culture. In the process the attention to values is reinventing an anthropological conception of culture by opening up new frontiers with once competitive uses of the term (e.g., Roy Wagner's argument about the relationship of anthropological cultures to high culture), while moving away from once prominent disciplinary interpretive vocabularies (e.g., Geertzian 'culture as text'). An ethnographic focus on ethics informs this disciplinary increase in values-talk, and supports new theory-building (e.g., new relations of the moral to the cultural). It has also informed how ethnographers engage indigenous legal struggles for identity and autonomy (e.g., the work of advocacy). All of this points to, in Zigon's words, the creative aspect of ethics as 'conscious work on the self.' Anthropology's more expansive turn to ethics, then, includes self-policing but also a growing appreciation for the ways ethics are theoretically productive.

Ethics along Emergent Frontiers

Revealingly, anthropology's ethics arguments often elide its ethical lexicon with the moral language of values, couched within a broader political critique of the behavior of states and of state institutions like military and security agencies. Ethical injunctions (e.g., against 'secret and clandestine' work) are represented as disciplinary 'core values.' And these core values define the possible extent of what anthropology can, or better, should be. As such, much of the back-and-forth of recent years has been over the extent to which the language of ethics effectively circumscribes the discipline as a self-reflexively moral community. As Lederman and others have emphasized (cf Plemmons and Albro, 2012), ethics, used as a linchpin to identify the core values of anthropology as a moral community, subjects disciplinary identity to its own emergent ethical theorizing in such a way that the discipline, itself, is presented as if a Sahlinsesque historically contingent cultural or moral order.

A distinguishing characteristic, then, of the ways that anthropology has taken up ethics of late is the regular interaction of these two modalities – the ethics of anthropology and the anthropology of ethics. And the discipline continues to complicate the historical 'duplexity' (Pels, 1999) of its relationship to ethics. Disciplinary ethical discussions at present combine appeals to extradisciplinary and impartial moral standards with political interests in the mode of advocacy, but now also with value-laden public commitments to anthropology as a historically contingent moral community – as a 'culture of research' shaped by the steady reframing of its ethics in terms of the unique particularities of ethnography and its incumbent relationships. A potential trap of the application of an anthropology of values to disciplinary practice is public disciplinary self-presentation, again borrowing from Zigon, as a 'unique local moral and ethical assemblage.' Increased public perception of the vernacularization of anthropology's ethics could, however, have the undesirable effect of undermining its standing as a social science.

At the same time, treating disciplinary ethics as occasional conflicts, regular debate, and moving frontiers is to imagine ethics as a necessary but fruitful source of vital disciplinary questions, knowledge and theory. The present review of several of anthropology's ethical genealogies, and of the dynamism of disciplinary ethical frontiers with science, diverse agencies of the state, bioethics, changing ethnographic relationships, normativities, and comparative moralities, points to the productive, theoretical, potential of regular ethical debate, a potential anthropological ethical researchers and theorists are now starting to realize.

And this is ongoing. One such ethnographically informed frontier is the more fluid disciplinary ethical conceptions of, and relationships between, privacy, secrecy, transparency, and new proprietary realities. If anthropology's relationship to secrecy has been fraught, this relationship is being creatively stretched by the changing shapes and meanings of 'openness,' now as incorporated in digitally-engaged 'open source' and 'open access' debates, ethnographic projects, collaborations, and new 'circulations of culture' (see Kelty et al., 2008). Current research and debate on openness is exploring often non-self-evident relationships to collective action, intellectual property, system standardization, interoperability, technical networks, free speech, collaborators now conceived as 'source communities,' and other new working relationships. 'Open access,' in other words, is one current and constructive source of ethical theory in anthropology's broadening relationship with its ethics.

Anthropological Writing

Abstract

Until the 1970s, the modal career in anthropology revolved around the regular publication of articles in scholarly journals, and the intermittent publication of book-length 'monographs.' Anthropologists now challenge the supposition that these two writing genres embody the only legitimate means to share knowledge. This article charts the variety of new modes of writing that anthropologists increasingly embrace – from memoir, biography, and fiction to flip books, graphic novels, and invented child care guides – as means to disseminate their findings and unique perspectives to broader readerships.

The Myopia of Monopoly

As Johannes Fabian has observed (2011: p. 16), the very phrase 'ethnographic writing' is redundant given that the Greek roots of the word 'ethnography' mean, literally, 'writing (about) people.' Despite this etymological foundation, the early decades of the discipline of anthropology saw little critical reflection on our writing practices. Instead, until the 1970s, the modal career in anthropology revolved around the regular publication of articles in scholarly journals, and the intermittent publication of a particular form of book termed the 'monograph' (Wulff et al., 2009). Typically, both writing forms featured a predictable structure. A general overview of a single, seemingly complete, and relatively isolated society classically preceded (or underlay) an analytic argument revolving around a basic theme, and one or more 'domains.'

Give or take the occasional effort to stray from the path of writing orthodoxy, both the article and the monograph typically relied on two problematic assumptions revolving around their literary production. First, our writing habitus normally presumed that the anthropologist-as-analyst was best left invisible to the reader, a scholarly Peeping Tom peering through the windows of the other's house. Second, we routinely took for granted that the cumulative emotional effect of this and other features of the work produced a reading experience that should approximate that provided by the natural science report more than that offered by the literary essay. Notwithstanding a few adventurous scholars, until recently the academy has largely left unchallenged, the grip that this model for the properly written scholarly article and monograph have long held on our discipline. To borrow a legal trope, the dominance of these two writing genres constituted a veritable monopoly.

Over a century ago in the United States, the Sherman Antitrust Act of 1890 effectively restricted the reach of monopolies in business; elsewhere, the US law has its analogue in most other modern nations (Joelson, 2006). By contrast, we have not yet passed our own Antitrust Act within the academy. Nevertheless, anthropologists have begun challenging *de facto* the supposition that the scholarly article and book-length monograph, structured in the ways summarized above, embody the only legitimate means for us to share knowledge. Equally important, we now question the notion that our fellow anthropologists constitute the only legitimate audience for our work. The remainder of this article explores the variety of ways that anthropologists are charting new paths in writing. As we have allowed ourselves to reimagine our writing practices, we have implicitly taken steps to embrace three new possible commitments: aiming our work toward new readerships; injecting new liveliness into the conventional writing genres of our discipline; and experimenting with writing in new genres for our discipline.

New Readerships

Central to the new ethnographic writing practices we explore in this article lies an increasingly urgent commitment to share our scholarly expertise with readers beyond our immediate colleagues (cf Gottlieb, 1997). Foundational to this trend lies a broader political commitment toward using our disciplinary knowledge to promote social justice.

Many scholars enter the field of anthropology in a quest to expose unequal opportunities – whether due to race, gender, sexual orientation, class, religion, health status, career choice, neighborhood, educational level, or other structural components of identity. After exposing such inequalities, many further hope that our writings might help expand opportunities for the disadvantaged – whether on a local, national, or global scale. Yet we have discovered that writing jargon-filled work destined for scholarly journals or book series that normally attract dozens or, at best, hundreds of readers limits severely whatever impact we may hope to have on whatever corner of the world (whether 'at home' or 'abroad') where we have chosen to focus our research. Frustrated by 'preaching to the choir,' we have begun expanding our 'bully pulpit' to new readerships (Sabloff, 2011).

The American Anthropological Association (AAA) – the discipline's flagship professional association in the United States, with increasing international membership (AAA, n.d.g), and the largest professional association in the world – now promotes this commitment in myriad ways. In recent years, the AAA has urged anthropologists to share our expertise with a broad public and increase our relevance, creating a host of new initiatives to offer realistic means for achieving this goal, including working with teachers from preschool to adult education classes (AAA, n.d.d), and encouraging anthropologists to read about and participate in public policy debates and other

work outside the academy (AAA n.d.a, n.d.c, n.d.e, n.d.f). Other smaller associations and entities likewise promote reaching out to broader publics in myriad ways, including sponsorship of book series aimed at general readers, and production of 'alternative' rankings of US doctoral programs in anthropology ranged according to the public effectiveness of each program's faculty, rather than the conventional academic criteria based on 'publications, status, and funds obtained' (Center for a Public Anthropology, n.d.). Outside the United States, many European, Latin American, and Asian scholars have engaged earlier and more comfortably with broader publics than have scholars than in the United States (e.g., Afonso, 2006; Barth, 2001; Eriksen, 2005; Hastrup et al., 2011; Hong Kong Anthropological Society, n.d.; Howell, 2010; Ribeiro, 2004, 2012; Rogers, 2001; Uquillas and Larreamendy, 2006).

Behind all these efforts – both collective and individual – lies not just the content of what we write, but the style of how we write it (Geertz, 1989). In effect, the above-mentioned initiatives, and others elsewhere like them, constitute a mandate for creating texts to engage readers beyond doctorate-bearing scholars. Insofar as writing is central to our scholarly practice, reaching new readers requires writing for those readers. How have anthropologists changed their writing style to make their message appealing to an 'educated public' that has an interest in an anthropological approach to understanding social life but lacks a doctorate in anthropology?

New Liveliness

An accessible text easily draws new readers to our research and our insights. And who are better than anthropologists to provide the comparative framework linking the global and the local, to humanize both near and distant others, to explain seemingly inexplicable behavior … in short, to propose creative ways to address the extraordinary opportunities and challenges of the twenty-first century?

Before the 1970s, the clamor for alternative writing remained marginal, with few feeling courageous enough to venture beyond the strict contours of the scholarly article or book; most saved the human stories-from-the-field for professional parties and the occasional classroom lecture. But the major cultural and political upheavals across Western societies during the 1970s saw echoes in major intellectual upheavals in the social sciences in general, and anthropology in particular – including upheavals in writing conventions. With the anti-Vietnam War movement, civil rights movement, women's rights movement, and associated 'sexual revolution,' growing interest in Hinduism and Buddhism, and development of alternative pop culture all combining to question long-accepted practices of both quotidian and political life, is it any wonder that anthropologists – observers of society par excellence – responded by questioning our own practices? The feminist revolution had an especially pronounced effect on our writing practices, although it took some time to be acknowledged (Gordon, 1988).

Unlike earlier generations, many junior scholars today aim to convey the sensory and emotional texture, and range of the human experience via a greater variety of textual styles. No longer are most of us content to write ethnographies that are, as Jeremy MacClancy wrote of an earlier generation of scholarship, "boring, and … virtually unreadable" (1996: p. 237). No longer do we consider it a badge of honor when a friend or relative expresses excitement on hearing about our research, only to confess confusion after dipping into our scholarly publications. Fewer among us feel content to exclusively write scholarly texts that turn off ordinary readers despite the inherent fascination of our topics.

Moreover, fewer academic publishers are willing to publish such works. It should be no surprise that good writing sells, and that means, in one way or another, good stories. Our species has aptly been dubbed homo narrans (Niles, 1999). Thoughtful observers of the human condition ranging from communication scholars (Fisher, 1987), literature professors (Gottschall, 2012), and psychiatrists (Coles, 1989) to urban planners (Eckstein and Throgmorton, 2003) and organizational sociologists (Gabriel, 2000) argue that storytelling is central both to our survival and to our nature. To sell more books, editors now advise authors via a simple homily: "More stories, less theory."

Many junior scholars are heeding the editors' advice. Increasingly, they express a desire either for a nonacademic career, or a career that combines academic research with nonacademic projects and publications. In both cases, their goal is to use their expertise to make a difference in arenas beyond the college classroom. Key to success in achieving this aim is honing the ability to write for readers beyond fellow scholars.

With this in mind, graduate students often seek out opportunities that will train them to hone their writing skills. In dissertation-writing workshops, students respond positively when urged to 'write from the heart' (Aronie, 1998) in turning their research data into theses. A long-ago piece of advice by the respected East Africanist, Ed Winter, may resonate today with doctoral students more forcefully than it did when it was first preferred over three decades ago (Gottlieb, n.d.).

"Don't look at your fieldnotes," Winter urged students just back from their field research. "Just write what you remember…You'll remember the good stuff. The important stuff. You can always check your notes later, make sure you got the details right."

If students were unlikely to take that antipositivist advice three decades ago, that is less the case today. Psychologists tell us that we humans live our lives at least as much in our feelings as we do in our thoughts (e.g., LeDoux, 1998). When neuroscientist Antonio Damasio (2010) studied people who could no longer feel emotions due to brain injuries, he discovered that these individuals had difficulty in making decisions about matters ranging from what to eat to where to live, despite being able to articulate rationally the advantages and disadvantages of their options. A recent theory of politics posits that a combination of emotion and reason accounts for the political stances we all take as citizens (Marcus et al., 2000). And within cultural anthropology, a growing number of scholars suggest that the same reality characterizes the methodological heart of our discipline – our fieldwork practice. That is, we bring our emotional biographies with us to the field, where they meet up with myriad emotional biographies of those in the communities we are studying (e.g., Ahmed, 2004; Hunt, 1989; Kleinman and Kopp, 1993; Kulick and

Willson, 1995; Wulff, 2007). However else we might portray it, the anthropological field encounter can be described as an emotional cauldron.

Anthropologists increasingly acknowledge that it does not make intellectual sense to divorce affective considerations from our analyses when they are a key component of the experiences that form the bedrock of our understanding. And given that narrative inherently offers the capacity to effectively evoke human emotion (Hogan, 2003; Hsu, 2008), anthropologists are increasingly discovering that narrative and related writing genres may actually offer more accurate – hence, more scientific – means for us as scholars to convey the full range of the human experience than do the conventional scholarly article and monograph. Echoing the wisdom of this growing interdisciplinary body of research, the best ethnographies, many now assert, engage our hearts and minds in equal doses.

In some cases, a traumatic incident in the field may so shake fieldworkers that they feel compelled to write about it in some deeply personal way. The usual distanced academic prose simply cannot capture enough of such events to satisfy either author or reader. For example, witnessing (or, in other cases, experiencing) sexual violence has produced riveting narratives by female anthropologists, who have drawn on their traumatic experiences to explore disturbing issues (di Leonardo, 1997; Winkler, 2002). Such emotionally engulfing events can be turned into compelling platforms from which to think frankly about the workings and bodily effects of power inequities, in ways that more conventional scholarly accounts cannot accomplish. Other returned fieldworkers may not experience such a single dramatic moment but nevertheless may have felt every aspect of newness so deeply, and listened so deeply to these feelings, that the cumulative result compels them to work through their emotions on the printed page. In either case, ethnographers who pay attention to the emotional core of their fieldwork experiences are likely to produce rich texts that leave an impact, and much to contemplate, well beyond the last page.

The mainstreaming of such texts signals important changes occurring in our discipline. The Victor Turner Prize in Ethnography (sponsored by the Society for Humanistic Anthropology, a unit of the AAA) has awarded $500 annually since 1990 for the most gripping ethnography published in the previous 2 years. As of 2013, 74 books have won a prize or honorable mention in the competition (Society for Humanistic Anthropology, n.d.). This corpus of engagingly written ethnographies suggests that many among the current generation of scholars seem inclined to write from the heart as much as from the mind.

For example, John Chernoff's two-volume biography of Hawa, a Ghanaian bar girl who is herself a storyteller's storyteller, by turns enchants, delights, and outrages the reader with a riveting account as hard to put down as the most gripping novel. The factual narrative describes an actual life that dignifies the particularities of a woman who has encountered and, in some ways triumphed over, hardships great and small. At the same time, the account evokes the challenges and life strategies of so many other working women whose lives are little short of heroic yet rarely generate written biographies (Chernoff, 2003, 2005). The rich ethnography conveyed by such accounts offers incomparable insights into the texture of human lives as lived in particular times and places.

The mandate to communicate our knowledge to a broad public becomes more realistic if we provide training for scholars in the writing skills that can convey the content of our research in an inviting manner. Thankfully, more scholars now teach such writing skills. Workshops on writing ethnographic fiction, poetry, and other 'alternative' genres are offered annually at the annual AAA conference (sponsored by the Society for Humanistic Anthropology), and they are increasingly oversubscribed. Moreover, semester-length courses on ethnographic writing are increasingly sprouting up in top-rated doctoral programs in anthropology across the United States and, more recently, in Europe. As such courses proliferate, programs increasingly train students to take the craft of writing seriously.

Writing for broad readerships lends itself to engaging with public issues and, in some doctoral programs, thus, goes hand in hand with a new emphasis on public anthropology (in the United States, as of this writing, in programs such as the University of Pennsylvania, the University of Oregon, Wayne State University, and the University of South Florida, among others). Such an emphasis characterizes doctoral programs beyond the United States as well. In Brazil, for example, "a minimum amount of advocacy on behalf of indigenous groups is expected…The lack of a dichotomy between 'getting involved' in the social and political struggles of study populations…and the academic ivory tower means that Brazilian anthropologists are university professors *and* political activists at the same time" (Chelekis, n.d.). Such a focus also characterizes a masters degree program in "applied anthropology and participatory development" in Australia, which is "designed for people working in government, non-government organisations, or as independent consultants … to manage development projects, including undertaking social assessment and advising on their cultural and social impacts" (Australia National University, n.d.). Such programs train students based on the premise that anthropological expertise in understanding the human condition merits promoting beyond the academy (on India, see Mahapatra, 2006).

In the United States, to increase the likelihood that the intellectual contributions of faculty in such programs receive proper recognition, the AAA has developed guidelines for tenure and promotion committees to use in evaluating efforts beyond scholarly writing (AAA, n.d.h, 2011). The AAA has also launched an online 'Writers Circle' that pairs scholars eager to write for a broader audience with seasoned scholars who have successfully done just that, and that makes such published writings available online as models (AAA, n.d.b).

New Genres

Anthropologists are staking out new territory by dipping into other genres, in a dual quest to reinvigorate traditional readerships and attract new ones. In the United States, Margaret Mead set an early precedent (e.g., Mead, 2005). Despite the many detractors who scorned the status she constructed for herself as public intellectual – especially through monthly columns in the popular women's magazine, *Redbook*, among other public venues – Mead established a powerful case for the relevance of an anthropological approach to

understanding the challenges of contemporary Western(ized) lives. Nowadays, after some especially vigorous critiques from colleagues, her intellectual legacy is being restored (di Leonardo, 2001; Lutkehaus, 2008; Shankman, 2009). Inspired by Mead's example, contemporary anthropologists are rediscovering that well-written editorial ('Op-Ed') pieces, letters to the editor, magazine articles, and radio pieces offer further tools to draw readers to our work. In the United States, a new Public Voices Fellowship Program (organized by an entity termed the Op-Ed Project) is providing training in just such genres: "This yearlong experience is designed to help professors…reach beyond the academic audience and share our ideas and experiences with a larger lay audience" (Colón-Ramos, 2013; *cf* The Op-Ed Project, n.d.). The Internet now offers unprecedented access to expanding readerships. Influential anthropologists such as Thomas Eriksen, Paul Stoller, and others now write blogs and guest posts for websites with enormous reach, while junior scholars experiment with new software programs to share findings in creative new formats (Balakian, 2011).

The classic genres of literature also offer appealing avenues for sharing our expertise. Early anthropologists such as Edward Sapir and Ruth Benedict published poetry that gained them readers beyond their scholarly colleagues (Caffrey, 1989; Flores, 1986; Handler, 1986). In recent years, cultural anthropologist Renato Rosaldo has won the widely respected American Book Award for his poetry (Rosaldo, 2003). Likewise, the early ethnographic novels of Adolf Bandalier (1971/1890), Ella Deloria (1988), Zora Neale Hurston (1937), and Laura Bohannan (Bowen, 1954) have many contemporary counterparts in novels by anthropologists Tobias Hecht (2006), Kirin Narayan (1994), Paul Stoller (1999, 2005), and others (cf. Laterz, 2007). Indeed, the Society for Humanistic Anthropology now offers annual awards in ethnographic poetry and short fiction, with winning pieces published in its peer-reviewed journal, *Anthropology and Humanism* (Society for Humanistic Anthropology, n.d.).

Beyond the two classic literary genres of poetry and fiction, anthropologists in recent years have begun exploring the possibility of sharing their expertise through other creative writing genres as well. Some anthropologists have written up their ethnography in the form of plays (e.g., Allen and Garner, 1997; Parada, 2008; Saldaña, 2005), mysteries (Nanda, 2009; Price and Price, 1995), biographies (Behar, 1993; Brown, 1991; Crapanzano, 1980; Shostak, 1981), and memoirs (e.g., Briggs, 1970; Cesara, 1982; Dumont, 1978; Gottlieb and Graham, 1993, 2012; Orlove, 2002; Stoller and Olkes, 1987; Tedlock, 1981).

Beyond these established writing genres, the world of writing offers a plethora of genres that we normally exclude from our scholarly purview, though we may engage them daily outside our academic lives. As participants in what we might term a veritable riot of literacy, scholars are intimately acquainted with a dazzling array of texts of every shape, size, and sort. Creatively engaging with such texts, some anthropologists venture beyond even the 'new' genres discussed above to create their own.

Back in the 1960s, not content with the conventional genres, the ever-maverick Gregory Bateson went so far as to invent a charming genre of writing that he called 'metalogues' (1972) in which he wrote partly fictionalized conversations about the most arcane of topics – conversations that he supposedly held with his partly imagined daughter (whose real-life model grew up to become anthropologist Mary Catherine Bateson). In recent years, a few experimental works by anthropologists and other social scientists have followed in Bateson's footsteps to draw creatively from other genres to convey ethnographic information in lively formats. Examples include a graphic exposition of the discipline (Galman, 2007), an imagined Socratic dialogue between European and African historical figures (Nzegwu, 2006), an extended photo essay (Behar, 2007), a political cookbook (Fair, 2008), imagined local child care guides *à la* Dr. Spock (DeLoache and Gottlieb, 2000), 'factional ethnography' (Sillitoe and Sillitoe, 2009), and an ethnographic, children's book-style 'flip book' (Taylor, 1998).

This growing corpus of 'alternative' texts suggests that increasing numbers of anthropologists are now 'finding their own jig to dance with genre.' As writing practices expand to attract multiple new audiences, the Internet beckons, with its extraordinary opportunities to find new readers. Anthropologists stand ideally poised to augment the discipline's reach in offering the insights into our lives as social creatures that are the hallmark of this unique academic field of inquiry.

Anthropology and History

James D Faubion, Rice University, Houston, TX, USA

Abstract

Anthropology engages history not as one but instead as many things: (1) sociocultural change or diachrony; (2) a domain of events and objects that make manifest systems of signification, purpose, and value; (3) a domain of variable modalities of the experience and consciousness of being in time; and (4) a domain of practices, methods, and theories devoted to the recording and the analysis of temporal phenomena. It emerged, and continues to serve, as that branch of 'natural history' which investigates the psychophysical origins and diversification of the human race. As 'ethnohistory,' it investigates the documents of the pasts of native or 'first' peoples, paying special attention to the dynamics and consequences of colonization. Emile Durkheim's *Elementary Forms of the Religious Life* (1995/1912) opens the arena of an 'anthropology of history' with its argument for the social causation of the experience and conceptualization of time, but anthropologists remain divided over what the anthropology of history is or should be. Their disagreements are instructive because they recapitulate a much larger and more enduring controversy over whether anthropological knowledge is a mode of historical or instead a mode of scientific knowledge. The controversy is probably also irresolute, at least until either anthropology or history comes to an end.

For anthropology, history is not one but many things. First, it is the past, especially the past that survives in archives and other written or oral records; 'prehistory' is its more remote counterpart. Second, it is change, diachronic as opposed to synchronic process. Third, history is a domain of events and artifacts that make manifest systems of signification, purpose, and value, the domain of human action. Fourth, it is the domain of all the diverse modes of the human experience and consciousness of being in time. Finally, it is a domain encompassing all those practices, methods, symbologies, and theories that human beings – professional academic historians among them – have applied to the collection, recollection, and comprehension of the past, the present, and the relations between the two.

Anthropology and Natural History

At the end of the sixteenth century, anthropology emerged in Europe not in contrast to history but rather within it. Thereafter, and for some two and a half centuries forward, it would broadly be understood as that branch of 'natural history' which investigated the psychophysical origins and diversification of the human race, or races, as was very often the case. Demurring throughout the period to the theological calculus of the creation of Adam, it confined itself to treating developments presumed to have transpired over only a few millennia. In 1858, miners at England's Brixham cave unearthed tools and other human remains that stratigraphers could prove to be at least 70 000 years old. Theological authority suffered a blow from which it would not recover; anthropological time suddenly acquired much greater archaeological depth. Meanwhile, a growing scholarly coalition was coming together to support the doctrine that 'culture' was that common human possession which made manifest the basic psychic unity of all the putative races of mankind. In 1854, James Pritchard would accordingly launch 'ethnology,' and send the racialists off on their separate ways (Stocking, 1987). 'Cultural' and 'physical' anthropologists would never again keep their earlier company. Yet, even through the turn of the twentieth century, natural history remained the largely uncontested source of the methods and aims of both. Questions of origin and development continued to have pride of place. The 'savage' or the 'primitive' became all the more entrenched as a disciplinary preserve, among other things as the rudimentary pole of any number of ambitious reconstructions of the probable steps or stages that had marked the human passage to 'civilization' or 'modernity.' E. B. Tylor's *Primitive Culture* (1871), Henry Lewis Morgan's *Ancient Society* (1877), and the several volumes of James Frazer's *Golden Bough* (1890) are classic examples of the genre.

Such far-reaching treatises would strike the more meticulous of the subsequent generation of their readers as undisciplined, even whimsical. By the 1920s, and despite all their other differences, Franz Boas, Bronislaw Malinowski, and A. R. Radcliffe-Brown were inaugurating a turn away from 'speculative history' in favor of meticulous observational attention to the 'ethnographic present.' Not even these sober empiricists were, however, opposed in principle to reconstructive or evolutionary analysis. With due regard for rigor, the more adventurous of their colleagues would continue to pursue it; and virtually every subfield of anthropology has contributed to it ever since. Physical anthropology is now a 'genetic' science in both the larger and the stricter sense of the term. Morgan's project survives most explicitly in the United States, from Leslie White to Marvin Harris, as 'cultural materialism' (see Harris, 1968), but also endures implicitly in the technological determinism that informs Jack Goody's argument in *The Domestication of the Savage Mind* (1977). Tylor and Frazer are the precursors not simply of Claude Lévi-Strauss's structuralism (see infra) but also of the burgeoning interdisciplinary and neo-Darwinist vocation known as 'evolutionary psychology.' Boas himself is among the bridges between an older 'comparative philology' and efforts to trace the family tree of all the world's languages (see Kroeber, 1935).

Anthropology and Ethnohistory

A more modest anthropological tradition of diachronic research has borrowed its methods less from natural history

than from empirical historiography. It has a partial foreshadowing in the particularistic study of the drift and dissemination of traits and artifacts from the centers to the peripheries of cultural production with which 'diffusionists' in England, Germany, and the United States were occupied between the 1890s and the 1930s. It has its more definitive commencement in the immediate aftermath of the Second World War. Its most familiar designation is still 'ethnohistory,' however misleading the suggestion of affinities or parallels with 'ethnoscience' or 'ethnomethodology' may be. In any event, the signature task of ethnohistory has always been the investigation and documentation of the pasts of those native or 'first' peoples whom anthropologists had until rather recently proprietarily or conventionally claimed as 'their own.' In the United States, its more concrete initial impetus came with the 1946 ratification of the Indian Claims Act, which soon led to anthropologists serving as expert witnesses – sometimes for the plaintiffs, sometimes for the defense – in the readjudication of the treaties of the pioneer era. In the United States and elsewhere, it would have a catalyst in the granting of public access to the administrative archives of the pioneers, the missionaries, and the bureaucrats of European colonization. Hence, its characteristic focus: the dynamics of contact and conflict between the subaltern and their would-be overlords: pioneering, missionary, colonizing, or enslaving (Spicer, 1975; Cohn, 1968, 1980; Leacock and Lurie, 1971; Rosaldo, 1980; Dirks, 1988, 2001, 2006; Kirch and Sahlins, 1992, 1994; Vansina, 2004, 2010; Hanks, 2009). The most wide-ranging examples remain Eric Wolf's *Europe and the People Without History* (1997) and Sidney Mintz's *Sweetness and Power* (1986).

Narrowly delimited, ethnohistory remains the specialist's craft. Since the 1970s, however, its methods and themes have met with an ever-widening embrace, and if 'historical ethnography' and 'historical anthropology' are not yet synonymous with standard disciplinary practice, they are certainly of a piece with it. The anthropological gaze is now less often 'from afar' than it is longitudinal. Such a vantage has been pivotal in the renovation of political economy. It has also brought fresh and stimulating perspectives to the address of kinship, race, national and personal identity, and gender (e.g., Stoler, 1995). Its deployment and impact may or may not be indications of greater disciplinary enlightenment, but they are by no means indications of passing intellectual fashion alone. The lengthening of the anthropological gaze has rather gone hand in hand with the ascendance of a postcolonial order in which social and cultural boundaries have become increasingly permeable and structures increasingly indistinguishable from processes. It has gone hand in hand as well with the ascendance of the postcolonial demand that anthropology offer a reckoning, not simply of its relation to the colonial past but also of the status of the knowledge that it claims to produce (Hymes, 1972; Asad, 1973; Clifford and Marcus, 1986).

Anthropology and Hermeneutics

In our postcolonial order, anthropology itself needs interpreting; so, too, do many other sociocultural phenomena. Anthropology's current troupe of interpreters espouses, however, an even stronger postulate: that sociocultural phenomena, as historical phenomena, permit only of interpretation; that they permit of contextual understanding, but not of general explanation. 'Interpretive anthropology' thus stands starkly at odds with the loftier versions of the natural history of culture, but further with any empirical historiography that has the inductive abstraction of general types or causal relations as its end. It now comes in many versions of its own. The most venerable of them commences with the Boasians. In 1935, Alfred Kroeber would accordingly remark that the ethnographies that Ruth Benedict and his other colleagues were busy producing were 'historical' in type. True enough, their temporality was synchronic, not diachronic. Their mode, however, was particularistic; their method contextualist; their analyses rarely if ever causal; and their model consequently that of what Wilhelm Dilthey, pursuing a 'critique of historical reason,' had defined as the *Geisteswissenschaften* – 'sciences of spirit,' literally, but better glossed as 'sciences of meaning' or simply 'hermeneutics' (Dilthey, 2002). In fact, Kroeber was quite correct; Benedict, Margaret Mead, and the other cultural anthropologists of Boas's circle were indeed hermeneuticians. They were hence establishing the methodological legacy to which Clifford Geertz is the most celebrated heir (Geertz, 1973). It should be added that the long-standing, if methodologically variable, tradition of life-historical or 'ethnobiographical' research, in which a limited diachronic inquiry serves as the means to a synchronically contextualizing end, is also Boasian in its widest parameters (see, e.g., Mintz, 1986; Crapanzano, 1980; Shostak, 1981; Faubion, 2011).

The more proximate wellspring of contemporary interpretation flows out of the tumult of the late 1960s. Elaborating in 1972 upon the call for a 'critical and reflexive anthropology,' Bob Scholte was among its earliest manifestologists, though he borrowed many of his own philosophical and methodological tenets from Johannes Fabian's slightly earlier exposition of Hans-Georg Gadamer's revision of Dilthey's thought (Scholte, 1972; Fabian, 1971, see also 1983). The channels thus opened have remained critical and reflexive, if perhaps not always so politically committed as Scholte might have hoped. Gadamer's heremeneutics has, moreover, served as only one of many subsequent grounds on which to establish interpretive license (see Rabinow and Sullivan, 1988). Walter Benjamin (see Taussig, 1993) and Giambattista Vico (see Herzfeld, 1987) have won admirers of their own. Geertz's inspirations were diverse: Suzanne Langer; Gilbert Ryle; Ludwig Wittgenstein; above all, Max Weber.

Such a well-populated census might suggest that, as much now as at its beginnings, anthropology belongs to history (as a discipline) no less than in it (as contingent process). Yet, even many of those who label themselves 'historical anthropologists' or 'interpreters' of one or another stripe would object to such a subsumption. No doubt, professional territorialism plays a part in their resistance. Often very palpable differences of professional sensibility play another part. Matters more strictly intellectual, however, play a part of their own, and their stakes are no more evident than within the anthropology of history itself.

The Anthropology of History

Durkheim's *Elementary Forms of the Religious Life* (1995) opens the arena of the anthropology of history with its argument for the social causation of the experience and conceptualization of time. Maurice Halbwachs' *Collective Memory* (1980) expands it and, after many decades of neglect, has come to be among the foundational texts of a recent surge of ethnographic and comparative inquiry into the techniques, the media, and the politics of remembering and forgetting (see, e.g., Boyarin, 1994; Shryock, 1997). Paul Connerton is the most systematic of Halbwachs' followers, and moves beyond Halbwach's own emphasis on the spatial objectification of collective memory to a consideration of the embodiment of memory in and as habit (1989).

The most imposing shadow hanging over the broader anthropology of history is, however, Lévi-Strauss's *The Savage Mind* (1966). A treatise devoted to the analysis of the analogical – and ahistorical – matrices of mythic and totemic thought, *The Savage Mind*, concludes with an extended polemic against the 'historical, structural anthropology' that Jean-Paul Sartre had advocated in the introduction to his *Critique of Dialectical Reason* (2004). Sartre had no time for totemists. His anthropology instead rested with the charting, and the heightening, of 'historical consciousness.' Against it, Lévi-Strauss had two general rejoinders. The first was that 'historical consciousness' was the expression not of dawning wisdom but instead of a collective devotion to 'development,' and its absence was not of the expression of error but instead of a collective devotion to homeostasis. Some societies ran historically 'hot'; others ran 'cold.' All were equally human. The second was that history – as narrative, as diachronic interpretation – was always 'history-for,' always biased. Stripped of its bias, it amounted to nothing more than the methodical application of temporal scales of measure to the flow of human and nonhuman events alike. If not that, then it amounted simply to the preliminary 'cataloging' with which any 'quest for intelligibility' – the anthropological quest included – had to begin. But it could be a beginning only: 'as we say of certain careers, history may lead to anything, provided you get out of it' (Lévi-Strauss, 1966).

Lévi-Strauss came to grant that his division between 'hot' and 'cold' societies was in need of much refinement; that instead of functioning as a strictly binary opposition, the division could better be conceived as defining a continuum. It is good that he did so, since a great deal of ethnographic evidence had already pointed and continues to point to just that. The classic cases are those of millenarian movements and so-called cargo cults, which have been widely documented in Melanesia and Polynesia (Worsley, 1957; Burridge, 1960, 1969), Amazonia (Hill, 1988), Africa (Peires, 1989), Native North America (Mooney, 1896), the Caribbean (Littlewood, 1992) and elsewhere, many but not all of them emerging in the aftermath of one or another colonial encounter and many but not all of them influenced by the New Testament Book of Revelation (see also Lindstrom, 1993; Faubion, 2001). Historically grounded studies of Christianization offer more complex versions of the same theme (Comaroff and Comaroff, 1991, 1997; Robbins, 2004). Michael Lambek has explored a decidedly non-millenarian but far from chilly sense of the relationship among the past, present, and future in Madagascar (2003). Penelope Papailias (2005) has delved into the writings of modern Greek historians to discover senses of the same relationship that are very far from the boiling point. The list could continue at length.

For all this, Lévi-Strauss never retreated from his division between historical and properly anthropological knowledge. On the contrary, from the outset of his career, he consistently counted history among those disciplines limited to the merely statistical representation and analysis of their objects. His anthropology is for its part a model-theoretic discipline, an axiomatic and deductive science. Its object remains what it was for Tylor: the psyche. Its quest, however, culminates not in the hypothetical reconstruction of the path toward enlightened modernity but instead in the formal exegesis of the universal 'grammar,' the structural and structuring properties, of the mind itself. 'Structuralism,' thus construed, is far less influential than it was in the 1960s, but by no means bereft. In 'cognitive anthropology,' it has its most secure contemporary home; and there, history (as intellectual or epistemological paragon) continues to meet with a cool reception.

For Lévi-Strauss as for other philosophical and scientific rationalists, there is an insuperable gap between the 'facts' and their theoretical intelligibility. For positivists and empiricists, the relation between facts and theories is putatively more seamless. Unabashedly positivist anthropologists are a rather rare breed at present, at least in the sociocultural field, though many cultural materialists and evolutionary psychologists might quietly reckon themselves as such. The positivist anthropology of historical consciousness or the 'historical sensibility' is rare indeed, but has a singularly unabashed spokesperson in Donald Brown. In *History, Hierarchy, and Human Nature* (1988), Brown offers a cross-cultural survey of those traits – from divination to record-keeping – most suggestive of a preoccupation with the meaning and significance of events. Among literate peoples, he discerns a relatively stable correlation: between the presence and prominence of such a preoccupation and the absence of caste or other fixed hierarchies. He concludes that history (as sensibility, as worldview, and as mode of inquiry) takes its most regular nourishment from an ideology of social mobility. Whether or not correct, the conclusion is compatible with Lévi-Strauss's own considered judgments. Here, too, the anthropologist takes history as an analytical object.

Marshall Sahlins offers an alternative, which also takes history as its analytical object, but further as its analytical mode. It preserves the structuralist principle that systems of signification are never mere derivatives of their social or material environment. Yet it casts them less as revelations of the grammar of the psyche than as interfaces or differentials between the past and the future of given social practice. Their effect is threefold. First, they determine the internal historical 'temperature' of practice, which is relatively colder when governed by prescriptions, warmer when not. Second, they vary in their capacity to accommodate potentially anomalous or disruptive events. They are more or less historically 'sensitive,' and the greater their sensitivity, the more the continuity of practice is itself at risk. Finally, they influence the symbolic 'weight' or import of actors and their acts. Where some men are

kings, and their authority unchallenged, the historian is right to monitor them with especial care; where democracy holds sway, he or she would do better to monitor status groups or classes or parties. Hence, the best historian should be a good anthropologist, and the best anthropologist always prepared to be a good historian as well (Sahlins, 1985).

Sahlins's standard of goodness is still the standard of objective accuracy. It thus stands in partial contrast to the standard that has at least implicitly guided interpretive anthropology since the Boasian 'golden age.' Though subject to diverse formulations – some more vividly critical than others – the latter standard is practical or pragmatic, a matter of consequences. Perhaps for a majority of interpretive anthropologists, it has been nothing short of 'liberation,' whether from psychosexual repression, as for Benedict and Mead, or from political domination and economic exploitation, as for Scholte. Many of its prominent inflections remain reformist, though of more qualified scope. For the Geertzian, however, the pragmatic proof of an interpretation lies in its facilitating conversation, its translational efficacy. For Geertz and others, it lies in a broadening or enrichment of our imagination of the ways of being human. For a few others still, it lies in therapeutic release – perhaps from prejudice, perhaps from alienated isolation. Interpretation must in every case be factually informed; but at its best, is always also 'informative.' Its analytical mode is historical; but however much Lévi-Strauss or Sahlins might disapprove, it is always also 'history-for' and 'anthropology-for' alike. So, too, the interpretive history of anthropology and the interpretive anthropology of history must occupy the same epistemological plane. Here, historical and anthropological knowledge are of precisely the same kind.

Consistent with such a position is Matti Bunzl's proposal for the development of a 'neo-Boasian' anthropology, a hybrid of the Boasian tradition of particularistic contextualization and Michel Foucault's genealogical 'history of the present' (Bunzl, 2003; Foucault, 1998). In Foucault's first sustained articulation of it, genealogy has as its exemplar Friedrich Nietzsche's *Genealogy of Morals* (1956). Following in Nietzsche's footsteps, it is grounded in the marshaling of evidence of the partiality of the presumptively universal. It exposes the contingency of the presumptively necessary. It is most definitely a history-for. It does not, however, offer a design for historical inquiry in close accord with Dilthey's or other standard historical precedents. It is 'meticulous,' but its aim is not merely nor even primarily to elucidate the contextual nexus that unites a historical ensemble into a meaningful complex. It is not hermeneutical in this sense. Its aim is instead to bring to light that one or another aspect of the present need not be taken as much for granted as at first sight it might seem to need to be. Bunzl rightly notes that the rhetorical force of Foucault's 'genealogy of the present' notwithstanding, it does not as a matter of its own methodological constraints arrive at the present as such. Bunzl's proposal is that a synthesis of Foucauldean genealogy and Boasian hermeneutics could yield a genealogical hermeneutics or hermeneutical genealogy not merely of the present but also in it.

Bunzl points to Paul Rabinow's *French Modern* (1989) as the first anthropological installment of a history of (if not yet quite in) the present. In the work leading to the publication of *Marking Time* (2007), however, and in the work since (Rabinow and Stavrianakis, 2013), Rabinow has been developing his own diagnostics not merely of the present but also of the near past that precedes it and the near future that might follow it. Drawing from Foucault but also from John Dewey and Gilles Deleuze, he offers an 'anthropology of the contemporary' that would track 'ratio(s) of modernity, moving through the recent past and near future in a (non-linear) space' and serving as 'gauges' in light of which one or another aspect of the modern can be registered as 'becoming historical.' Once again, a history-for but also as much an anthropology-for, it borrows some portion of its critical framework from Foucault's late formulation of a 'critical ontology of ourselves,' an exercise that in its successes would extract 'from the contingency that has made us what we are, the possibility of no longer being, doing, or thinking as we are, do, or think' (1997). If the specific temporality of Rabinow's anthropology of the contemporary is of modest scope, it is in accord with the modesty that Ulrich Beck et al. (1994) have implicitly endorsed in their account of the 'risk society' in which we now all live and that Niklas Luhmann (1998) has similarly endorsed in his account of the increasingly global 'ecology of ignorance' with which we now all have to cope. Both accounts underscore that relations between the recent past and the near future are about the only relations in whose understanding we might dare to have some confidence. Contemporaneity is thus our lot. It is the distinctive order of the day. An anthropology of the ratios between the recent past and the near future could accordingly be thought to afford an analytical lens through which we might examine the environment – epistemic, sociocultural, and political – that is in fact all of our own.

In any event, it is clear that history is not simply a thing of many anthropological refractions. It is also a thing of plural and incompatible anthropological estimations. These in turn are among the most telling indices of the most persistent and most persuasive of plural and incompatible visions of the basic enterprise of anthropology itself. One can hence condemn the discipline for its intellectual indecisiveness or incoherence. One can applaud it for its perspectival diversity. One can in any event note that its many byways have a common point of departure in the question of whether human nature itself is transhistorically fixed, or instead historically variable. This is anthropology's first question, and if the past is any indication of the future, it is likely to remain so, at least until either Man or history comes to an end.

Anthropology at Home

Sophie Chevalier, Université de Franche-Comté, Besançon, France

Abstract

Distinction between doing research at home and among the others is built into the social sciences as a division of labor between sociologists and anthropologists. Anthropology at home runs counter this distinction, historically based on the Great Divide between 'us' and 'them.' Yet more and more anthropologists work today in their own society and the gap between self and other is maintained less sharply than in the time of empire and nation-building. The decentred comparative perspective that goes with an ethnographic sensibility can be brought to bear on everyday life anywhere, including on the more familiar institutions of mainstream urban life.

Introduction

At one level, the distinction between doing research at home and among the others is built into the social sciences as a division of labor between sociologists and anthropologists. This is despite their historical unity as 'comparative sociology' in the work of Durkheim and Radcliffe-Brown. Thus for Claude Lévi-Strauss (1958), the sociologist observes his own society or one like, while the anthropologist tries to make sense of other cultures. The latter consists of taking a 'view from afar' on these societies, a perspective on the Great Divide between 'us' and 'them' that was intrinsic to colonial empire. Yet more and more anthropologists work today in their own society and some traditions, such as the French, have done so since the beginning, largely as part of its own nation-building project. As a field with the wider discipline, therefore, 'anthropology at home' can be complicated. Apart from anything else, working in one's own country, especially when it is large and diverse, may not count. The term is more likely to be used in countries that once had foreign colonies to denote a gaze turned inward rather than outward.

Ethnography is a method now used widely in the social sciences. Anthropologists have long claimed that their version of it was distinctive in at least three senses: their 'view from afar' allowed them to juxtapose the familiar and the unfamiliar in interesting ways; they always tried to fit their concrete observations into a wider social or cultural whole; and they brought to their ethnography a range of highly contrasted comparative examples. 'Anthropology at home,' the idea of a native working in their own society, runs counter to most of this, insofar as everything is or ought to be familiar, society as a whole is harder to envisage and the comparative method draws more on books than the fieldworker's own experience of contrast. The kinds of knowledge accessible to 'natives' and 'outside observers' are held to be significantly different; and certainly Lévi-Strauss reinforced this separation in contrasting structural anthropology with sociology. Of course, this is all connected to making the universalizing claim to capture the human experience in general, rather than just describe particular instances of it. As a result, anthropologists working at home have several techniques available to reintroduce a comparative perspective – through studying classes other than their own or adopting a historical approach. This was in fact the case with the first folklorists in Europe when they inserted themselves into rural worlds, other with an evolutionary paradigm in mind. Today, long after the collapse of European empires and of the rural/urban divide, the decentred comparative perspective that goes with an ethnographic sensibility can be brought to bear on everyday life anywhere, however familiar or unfamiliar the circumstances are supposed to be.

The idea of territory – and national territory in particular – is central to anthropology at home. In former imperial countries like France and Britain, metropolitan society was opposed to the colonies abroad which were considered to be the main source for a general social anthropology because they provide simple models of our complex civilization. Later of course, when members of the former colonies migrated in numbers to metropolitan countries, they provided objects of study at home whose cultural difference from the ethnographers introduced further confusion in the inside/outside dialectic of modern anthropology.

At this point, we will have to draw some lines around our topic. There are several very large countries – such as the United States, India, China, Brazil, and Russia – whose anthropologists worked within their own national territory, but mainly with groups considered to be external to mainstream society, perhaps as exotic as Pacific islanders to European colonists. These anthropologists could not be thought of as doing anthropology at home on remote hill tribesmen or Amazonian hunter-gatherers. In societies without external or internal colonies, anthropology at home was linked to the process of nation-building. In recent decades, all these societies have seen a shift to doing anthropology anywhere, including on the more familiar institutions of mainstream urban life. The typology of overseas empire, inland empire, and nation-states is not hard and fast; but in this article, I will focus on anthropology at home in the first and third types, less so in the second, but always with a regard for recent developments which have eroded such distinctions to a large degree. This means that my focus will largely be on Greater Europe (including Russia). We should also note that our subject has appeared under a number of different names: folklore studies, *Volkskunde*, ethnography, *ethnologie*, or anthropology at home.

In the four main schools which formed modern anthropology – Britain, France, Germany, and the United States – a variety of approaches to anthropology at home developed,

always keeping in mind George Stocking's (1982: p. 172) distinction between nationalist ('nation-building') and imperialist ('empire-building') strands that have shaped the discipline, sometimes separately, sometimes combined, but with different emphasis.

Anthropology at Home in France and United Kingdom

The intellectual and institutional context for the emergence of anthropology at home is very different for Britain and for France. There was, for instance, no classical school of British sociology. The founders of the British school of ethnographers sought to differentiate their discipline, as a kind of comparative sociology, from ethnology or folklore; and while British folklorists focused primarily on their own country, social anthropologists worked in faraway overseas. But folklore never evolved into a modern academic discipline under any name.

In a review of British intellectual life, Perry Anderson (1968) contrasted the British situation with sociology in continental Europe and North America, which took root as a conservative discipline celebrating the achievements of the bourgeoisie. Anderson argued that the British ruling class had no interest in social conditions at home, but instead promoted social anthropology as a means of studying the peoples of the Empire. This presented itself as 'the sociology of primitive societies,' basing its claim for universality on the presumption that social order everywhere was revealed most clearly in 'simple' societies (a notion shared by Durkheim and Mauss).

So British social anthropology in its prime did not have to distinguish itself from sociology and folklore was a weak competitor. As late as the 1960s, anthropologists took up posts that might otherwise have been filled by sociologists. Despite the relatively open field, British anthropology at home was slow to take root in the main centers. It was encouraged only by Max Gluckman's department at Manchester, which combined social anthropology with sociology. As a result, the leading figures of British anthropology at home, such as Ronald Frankenberg and Anthony Cohen, started out there.

In France, however, anthropology did not benefit from the expansion of the universities in the 1960s, in striking contrast to sociology. Whereas exotic anthropology in Britain long enjoyed an unchallenged monopoly, ethnologists working at home in France had to compete with both exotic anthropologists and sociologists. Sociology has long been the strongest social science discipline in France and ethnology was always on the defensive there, as it is today. 'The ethnology of France' has long been hidden away in corners of the universities, a marginal field that never had distinguished chairs similar to those held by professors of Volkskunde in Germany. Whereas the latter played a major part, with history, in nation-building, in France, history and geography dominated studies of the national question. Ethnographic descriptions of France and folklore museums were rare at the end of the nineteenth century; and anthropology at home slowly built a reputation as a legitimate discipline and source of collective memory in the interwar period.

In both Britain and France exotic anthropology led the way; the Institute of Ethnology in Paris catered exclusively for ethnography in the colonies and the ethnology of France struggled to establish itself. Both colonial empire and nation-building posed problems of reconciling political imperatives with scientific practice. This was particularly acute when the idea of citizenship and the national territory itself were at stake. In both countries, the scientific and political projects of exotic anthropology found a measure of convergence, but in France this convergence also took place at home.

The study of French history and society was placed in the service of the Republic. National feeling was always modified by attachment to one's 'little homeland' or local identity. Regionalism, starting out as a literary movement, remained loyal to the republic, even if tensions between the regions surfaced here and there. Indeed after the war regional chauvinism was a way of showing pride in being French which has generally managed the tension between centralization (jacobinism) and regionalism. Only during the Second World War did the Vichy regime require social scientists to separate their science from the republican ideal. The period immediately after the war saw an acceleration of the transition from folklore (the term vanished after 1945) to an ethnology of France influenced by social anthropology.

Arnold Van Gennep played a particularly significant role in the development of the anthropology at home in France, acting as a bridge between folklore and ethnology and, with 'rites of passage' was the first to coin a concept for the study of Europe that was taken up by the exotic anthropologists. But he never had a real job and remained marginal to the Durkheimian establishment all his life. In Britain, history and political geography always constrained anthropologists to express themselves with caution when addressing the national question and regional attachments were never part of nation-building.

The ethnography of Britain is a fragmented field, for sure, and its visibility was for a long time very weak. But the disciplines were much less closed there. Individuals and the contexts in which they work are more open to interdisciplinary collaboration in Britain, whereas their French counterparts withdrew into relative isolation from the 1970s. Anthropological dialogue with geography, psychology, and sociology was a hallmark of British studies published during the 1950s. Despite intensified policing of disciplinary boundaries since then, cross-fertilization has continued and it clearly adds to the strength and wider influence of British social anthropology. Today, many anthropologists whose primary interest is Britain, work in departments other than anthropology, where they develop successful collaborative relationships.

British ethnographers also became interested in cities long before their French counterparts. Urban and even industrial research was launched in the 1950s: they were looking at urban life, focusing particularly on kinship, which was seen to provide the framework that made the sprawling metropolis manageable. Engagement with novel field situations, compared with the classical village sites, led British anthropologists to be more innovative in their approach and at an earlier stage. French ethnologists, on the other hand, were penned into their rural worlds for much longer and were slow to visit the city. This is surely one another major contrast between the two countries.

In both, the rise of anthropology at home was linked to the end of colonial empire. For a long time doing fieldwork in one's own society was a way of either getting started before

doing the real thing abroad or of making do at home when exotic fieldwork was no longer possible. Only in the last three decades have significant numbers of anthropologists in both countries carried out fieldwork at home, with the result that these domestic efforts are now beginning to have a theoretical impact on the discipline equal to that of exotic ethnography.

British social anthropology's early emphasis on studying what were presumed to be 'simple' societies was reflected in the fact that much of the ethnography of the British Isles started in the Celtic margins – especially Wales and Ireland – which were considered relatively remote and undeveloped. The first fieldwork-based studies of British societies were undertaken by North Americans. But anthropology at home in Britain took off with the publication in 1957 of Frankenberg's 'Village on the Border.' From the 1960s, some British social anthropologists were influenced by more cultural perspectives: studies of 'community' brought a discourse of 'belonging' into considerations of identity in Britain (Cohen, 1982). Anthropologists discovered that cultural difference easily survives in the face of the homogenizing forces of modernity: this celebration of British cultural heterogeneity also contained more than a hint of nostalgia and salvage ethnography.

French ethnologists too cultivated the social and cultural margins long before they entered the city. If French research at home got going a lot earlier, its institutional framework encouraged collective work and was less reliant on individual initiatives than the British. The National Museum of Popular Arts and Traditions launched a number of large-scale team exercises in the 1930s, such as one in Sologne with Malinowski and Dumont, long-term studies of rural architecture and technology during the war and finally the Aubrac study of 1964–68. Other research centers undertook similar studies, such as the big interdisciplinary project at Plozévet (1960s), exploring a theory of biological anthropologists about a deformed hip common among the women of the region. By contrast to their British counterparts, French ethnologists left reflections on social class to the sociologists, and gender roles were taken up in France only at the end of the 1970s. From the 1980s onward, as a result of government policy, ethnologists were integrated in research programs organized around an interdisciplinary theme such as skills seen in a heritage context. A number of ethnologists today work on heritage and the history of anthropology.

Since the 1970s, there has been a convergence in both countries between the exotic and home branches of anthropology. In Britain, the earlier emphasis on comparative sociology has given way to a cultural anthropology influenced by French structuralism and American symbolic anthropology. Kinship was the focus of French ethnology's self-renewal in the 1970s, under the influence of Lévi-Strauss's social anthropology. The outstanding work of this period was carried out by 'the Ladies of Minot,' members of the Laboratoire d'Anthropologie Sociale, within the framework of the Châtillonais team project, which brought the basic themes of exotic anthropology – kinship, ritual, identity, and socialization – to the ethnology of France. All of these studies were of rural areas. Only from the early 1980s did French ethnologists begin to take an interest in the city, industrial life, ethnic groups, sport, and complex organizations, in short the whole range of social practices or almost so.

In both France and Britain today, anthropology at home is now flourishing, drawing on each other and on their fellow branches in the rest of Europe. One can identify two trends in the dominant anthropological approaches of both countries. One, the majority, is still concerned with trying to understand the properties of social and cultural groups through the articulation of individual actions with collective structures. The other, identified with a branch of French sociology and some anthropologists in Britain, has abandoned entirely the ambition of locating its findings within any notion of social structure, being concerned with specific practices that individuals have in common, sometimes without even locating these in time or space, never mind in society.

'Anthropology at Home' in the Rest of Europe

The majority of schools in the rest of Europe may be summed up as 'nationalist anthropology' in that they were strongly influenced by the contingencies of national political history. The details of each case lie beyond the scope of this essay; but it is possible to identify some common strands by highlighting the formative example of Germany, followed by Russia's influence after the formation of the Soviet bloc.

According to Gingrich (2005), the German Enlightenment tradition of anthropology turned to introspection in the nineteenth century, first by giving priority to German rather than non-German topics and then to spirit and soul rather than the facts of what people really do. This trend combined with the concept of *Kultur* developed by Herder – a key figure in the history of German anthropology – in which he emphasized languages, customs, and mentalities to arrive at an ethnocentric division between German and nearby European *Kulturvölker* and most of the others (*Naturvölker*). Early anthropological writing there had little to do with colonialism (Germany acquired some colonies in Africa only after 1884). The preeminent tendency was to look inward, promoting historicist folklore studies with a nationalist flavor. Eventually, this led to a separation between folklore studies at home (*Volkskunde*) and ethnology aboard (*Völkerkunde*). Ethnography as such was more common in the latter.

As Arendt (1958) shows, the Romantic imaginary of nationalism in the German-speaking countries – and in most of the Central and Northern European countries – was perceived as a return to the nation's alleged rural roots. Rural folklore studies were thus linked to a mass movement whose inspiration was literary as much as anything else, the great fairy tale collections of the Grimm brothers being the prime example. Folklore studies were a form of historicism and even today, *Volkskunde* has remained strongly attached to historical methods and to the academic field of history. At the margins of the German-speaking world, popular and academic folklore studies were less nationalist and more interculturally oriented: Switzerland and Austria stand out in this respect, one as a multicultural democracy and the other as the center of a multinational empire. In Poland, Hungary, and Czechy, ethnography was linked to a movement for national independence. This is why, from a methodological perspective, Gellner (1959) locates the intellectual roots of ethnographic fieldwork in Central Europe at the turn of the century.

Anthropology at home in Central Europe, with its core in folklore studies, was separated intellectually and institutionally from anthropology abroad, but it also had no relations with sociology or with the long debate over the future of the peasantry ('the agrarian question' launched by Lenin, Kautsky, and Chayanov) before the 1970s. In the twentieth century, the two branches of German anthropology were likewise detached from mainstream developments in international sociocultural anthropology until the same period. From the 1930s, anthropology and folklore studies were smoothly integrated into the Nazi project. They became inseparable from physical anthropology, which was now the main scientific arm of this racist ideology. Folklore studies were also integrated into a pangermanic project, including the study of German minorities in Central Europe: ethno-cartography and folkloric atlases were their principal tools. Empirical studies were also carried out in several countries aimed at establishing a 'New European order' with Germans at the top.

The new intellectual environment after the war saw *Volkskunde* persisting separately in Germany until the late 1970s, but now influenced by new concepts and methods in history such as 'history from below.' The leading figure here was Hermann Bausinger in Tübingen who transformed folklore studies from a nationalist approach into a fieldwork-based ethnography of sociocultural process at home. The name changed too from *Volkskunde* to *Europaïsche Ethnologie* which made it a serious partner for sociocultural anthropology until now. The objects and methods of these anthropologists scarcely differ from those of their colleagues who work outside Europe, except perhaps for their emphasis on history.

Scandinavian anthropology went through a similar transformation. The division between anthropology at home and abroad continues there, with local variations, but always with a national, even nationalist dimension. Moreover, there was little or no indigenous tradition of sociology there. The Nordic countries – Sweden, Finland, Denmark, Norway, and Iceland – were influenced at first by German intellectual life and so anthropology found its inspiration there; but after 1945 it developed in different directions in each country. Anthropology at home, however, increasingly took its concepts and methods from the general international discipline from the 1960s. Thus in Sweden before that time, 'studying the life of the people' (*Folkslivsforskning*) was a department attached to a section of the Nordic Museum. Borrowing the concept of 'community' from the Anglo-Saxons facilitated this transition. Although the institutional separation between departments of ethnology and anthropology may persist, working on one's own society is no longer restricted to the ethnologists.

The countries of Central and Eastern Europe came under a double influence: German before the Second World War and Soviet after it. We might speak of a third influence today, the global hegemony of American anthropology. Poland is a case in point. Folklore studies were an instrument of national survival after the country was carved up between foreign powers, being essential to an ethnic nationalism whose object was to raise national consciousness through a revival of peasant traditions. After the First World War, Polish anthropology was renamed as ethnology and it combined the science of peoples with the science of the people (*Völkerkunde* and *Volkskunde*). But after the Second World War, Polish anthropologists, along with other countries of the Soviet bloc, adopted the term ethnography for their discipline. This was intended to highlight the dialectical unity of fact (*-graphy*) and theory (*-logy*) in research. Ethnology made a comeback in the 1970s. Then after 1989, departments were renamed as 'ethnology and cultural anthropology,' indicating an openness to both the European and Anglo-American traditions.

In Hungary, the term *néprajz* (description of the people) denoted an ethnography aimed at documenting the phenomena of Hungarian popular culture that was based on fieldwork, analysis, and comparison of these phenomena. *Egyetemes néprajz* (universal ethnography) included studies undertaken outside Europe. As in Poland, the origins and development of ethnography were linked to the politics of external domination, with the objective of establishing the authentic character of Hungarian culture linked to its origins in the history of the Magyars. Ethnography was devoted to studying Hungarian popular traditions in the countryside, but also took in other peoples who lived in the same political space. Fascination with peasant culture carried over into music through the great twentieth century Hungarian composers, Bela Bartok and Zoltán Kodaly. Peasant studies during the socialist period allowed Hungarians to highlight national identity while observing the restrictions placed on their discipline by the regime; they were even able to study religion under the guise of 'survivals.'

Similarly in Bulgaria, for example, from the 1960s, folklore studies allowed anthropologists to study national roots without exciting the suspicions of the ruling party. These studies included religious icons, material culture, music, and popular literature. The school of descriptive ethnography which flourished in Czechoslovakia still exists, but research there tends to be focused on oral literature. Gradually, methods developed for the study of popular literature were extended to other subjects.

In Russia, then in the Soviet Union, anthropology at home has been through ups and downs, which at times came close to its being banned. Of course we are dealing here less with a national tradition, more with several waves of inland empire. Expansion toward the East led the Russian tsars of the nineteenth century to establish museums and similar institutions to organize ethnographic studies. Peter the Great founded a museum of foreign cultures in the Russian empire in 1714; another, also in St Petersburg, was founded in 1895 to exhibit collections from the various peoples integrated into Russia. A strong institutional distinction, which exists today, developed between those who studied Slavs – anthropology at home – and those who worked on other peoples incorporated into the Soviet Union. The revolution itself did not disturb this work, but things became serious by the end of the 1920s. Researchers could continue their work on peasant traditions as long as they were far from the center. This led to the publication of major works by Zelenin (1927) on the eastern Slavs (a book banned in 1929 and republished in 1991) and above all by Propp (1928) on the morphology of folktales which was very influential. Eventually ethnography came to be seen as a bourgeois science and some anthropologists were forced to give up their work or to go into exile. Those who remained were discouraged from drawing attention to 'retrograde' elements of popular culture. They tended to show that peasants remained

strongly attached to their traditional culture and were largely immune to modernization and to socialism. Obviously, drawing attention to religious 'superstitions' was out. As a survival strategy, ethnographers had to keep their heads down, for example, by working in institutes not ostensibly concerned with ethnography or by taking refuge in provincial universities. Sometimes these strategies succeeded, as in the case of the Tartu School in Estonia whose work on the semiotics of culture had a significant influence in the countries of the Soviet bloc. It was recognized and approved in 1970 and gave rise to a new subject, 'culturology' that links semiotics to a broader definition of culture.

Several new research themes have emerged since 1989: religion, in particular the role of orthodoxy in Russian identity; Soviet 'traditions' and the political manipulation of traditional culture in the socialist period; and the social transformations brought about by recent political and economic change.

American Anthropology

American anthropology was late to arrive on the international academic scene and a lot of foreign-born or trained scholars played a critical role in the discipline's development there. Although the early American anthropologists tended to work within their national territory, their focus was mainly on the Amerindians who certainly did not share the notion of belonging to the same nation (many of them were employed in the Indian service). Some worked on immigrant groups and small towns in a process that might be likened to nation-building; others on neighboring countries, Mexico in particular. Rather than stress anthropology and home and abroad, American anthropologists, with their four-field approach, preferred to make a distinction between simple and complex societies of the kind that sustained ethnography in the British and French colonies. Venturing abroad or studying 'complex' societies was a big step for American anthropologists. The urban sociology of the Chicago ecological school was part of a joint department with anthropology, so that the city's neighborhoods were studied side by side with Mexican peasants.

The main impetus for work inside the United States came from Melville Herskovits' pioneering studies of race relations and communities studies such as Robert Lynd's in Middletown which was itself modeled on Robert Redfield's study of the rural–urban continuum in Mexico during the 1920s. From the early 1930s, urban communities were studied by anthropologists, such as William F. Whyte's (1943) innovative study of an Italian slum in New York city. Many of these small-scale ethnographic studies addressed problems of contemporary American life, such as class, race, and sometimes the power structures and economic organization of these communities. During the 1960s, two trends dominated research carried out in the United States: urban anthropology and studies of ethnicity studies, each stressing the multiplicity of cultural groups coexisting within national society. An exception to this was David Schneider's more traditional study of kinship in Chicago which was intended to be part of a comparative project with Raymond Firth in London.

Whatever the relevance of the distinction between doing anthropology at home and abroad, it has vanished since the 1980s when anthropologists everywhere, but especially in the United States, discovered that we are all living in one world unified by neoliberal globalization. So they studied that.

Specific Institutions

For anthropological practice to take root in a national territory, as opposed to abroad, requires institutions able to support specialized researchers and to communicate their results to a public. This means museums, universities, research centers and journals, as well as umbrella organizations. In regions like the former Soviet bloc, specialized institutions would be part of an overarching Academy of Sciences. There is a section of the French Ministry of Culture called the *Mission du patrimoine ethnologique* (Mission for the ethnological heritage) which was created in the 1980s to promote and fund research on France.

Museums

Museums have played a crucial role in sustaining anthropology at home everywhere, usually focusing on the material culture of the people studied. Museums of this kind had their origin in competition between European nations. In countries which distinguish between anthropology at home and abroad, there are usually two distinct types of museums corresponding to this division.

Museums in France and Britain illustrate the general point and the contrast between the two countries. Both countries developed local and regional museums – the Welsh Museum near Cardiff was an early pioneer in Britain, in contrast to the British Museum and other imperial collections in London, and the Museon Arlaten in Arles was founded in 1899. The National Museum of Popular Arts and Traditions (MNATP) eventually broke away from the Trocadero museum in Paris (later the *Musée de l'Homme* and now the *Musée du Quai Branly*) which specialized in exotic anthropology, but had a 'French hall' since 1884. The MNATP was formed as an independent institution in 1938 to encourage and shape ethnology in France; it finally had its own building in 1969. It was at first modeled after the Scandinavian example and later the Soviet Union and Germany (*Heimatmuseen*). It aimed to provide a national synthesis of 'rural material civilization' and it took charge of all regional and local museums. The museum was closed down in 2005 and its collections moved in 2010 to Marseille, where it is now being transformed into the Museum of European and Mediterranean Civilizations. The idea of a national museum of ethnology never took off in Britain.

Most of the other European countries have some kind of National Museum of popular arts or ethnography, for example, Bucarest's Museum of the Peasantry, the Museum of Ethnography in Kiev and Budapest, and numerous local museums or *Heimatmuseen*. All of these museums share the objective of integrating popular traditions in all their variety into the national culture. Since the nineteenth century, these have been complemented by open air constructions exhibiting the diversity of national architecture in one synthetic site, the leading

example being Skansen in Sweden (1885). A development of this idea later was the 'ecomuseum' which sought to present a particular territory through everything it contained. Museums, more than anything else, entrenched the deep split between 'exotic' and 'popular' material culture that has characterized anthropology in Europe ever since, in the process undermining anthropology's pretension to being a universal discipline.

In a few countries, especially the United States, one can also find community museums, which allow these places to portray their own role in national history.

Associations and Journals

Anthropologists are organized in professional associations at different levels: regional (European Association of Social Anthropologists-EASA); national (American Anthropological Association, Association of Brazilian Anthropologists, etc.); and topical (medical anthropology, anthropology of religion). Inside these big associations, there are sometimes sections concerned with 'anthropology at home' like the 'Europeanist network' of the EASA whose members usually work in their own country. Some associations are explicitly specialized on anthropology at home like the *Société d'Ethnologie Française*. But more and more, these kinds of associations take a wider geographical area. The *American Folklore Society*, for example, defined itself as an association of folklorists whose members study and communicate knowledge about folklore throughout the world, and not only in America. But this association's publications have retained a strong historical approach.

Most associations publish journals which are rarely today restricted to 'anthropology at home,' despite their titles, *Ethnologie Française* being a case in point. This journal now publishes European ethnology and sometimes papers based on research carried out outside Europe; but in general, the majority of issues have a regional focus, such as 'Ethnologia Europaea' or 'Ethnologia Balkanica.' All of this points to the growing difficulty today of maintaining a clear-cut distinction between anthropology at home and abroad. One might indeed ask if there is indeed a future for 'anthropology at home.'

The Future of Anthropology at Home

In the twenty-first century, most ethnographers work in their own country and the gap between self and other is maintained less sharply than in the time of empire and nation-building. The dominance of European and American anthropology is now challenged by the rise of emerging societies, such as Brazil, India, Mexico, and Nigeria, as well as by the residue of British Empire in Canada, Australia, and South Africa. Anthropology might be said to be more dynamic in these places than in the old imperialist centers. In some cases, such as India and Nigeria, anthropologists cultivate a traditional niche, studying remote tribal groups that are still perceived as requiring integration into national society. In China, anthropology is concerned with the 7% of the population that is not Han. The rest is the domain of sociology. Brazil now has the second largest anthropology association in the world. Until recently, the bulk of research there was carried out in Amazonia – and this is still the case for the National Museum in Rio de Janeiro. But Brazilian anthropologists have taken advantage of the rigidity of neighboring social science disciplines, sociology, and political science in particular, to enter the field of contemporary urban society and culture, with impressive results for their national visibility. Of course, such incursions into home society are no longer separated institutionally or theoretically from a world anthropology that studies people everywhere; and in this respect, the anthropology of emerging countries resembles Europe at the present time.

We should never forget that relations between ethnographers, their subjects, and their readers have changed profoundly in recent decades, all of which has altered the status of anthropology at home as opposed to anywhere else. Anthropologists study here and there. The anthropologists themselves come from here and there. Maybe we will soon discover that everyone needs to feel at home in the world.

Anthropology, Genomics, and Human Variation: National Roots

Gisli Palsson, University of Iceland, Oddi, Reykjavik, Iceland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Emphasizing concerns with cultural identity, belonging, ancestry, and health, this article discusses the national roots of the science of human variation and differences, focusing on the significance of genomic studies for national projects and the significance of national concerns for genomics. This is illustrated through a discussion of national biobanks, genomic projects, and genealogical databases, while highlighting purposes, limitations, and future scenarios.

Introduction

Emphasizing concerns with cultural identity, belonging, ancestry, and health, this article discusses the national roots of the science of human variation and differences, in particular anthropology, focusing on the significance of national concerns for genomics and the significance of genomic studies for 'national projects,' for attempts to identify and manage national bodies, populations, and identities – in sum, for nation building. This is illustrated through a discussion of national biobanks, genomic projects, and genealogical databases, while highlighting purposes, limitations, and future scenarios. From the beginning of national projects, with the emergence of nation states and empires, phenotypic markers (skin color, hair texture, skull shapes, etc.) played important roles in identifying and demarcating social groups and for establishing criteria of citizenship (Lindee and Santos, 2012). While national projects were focused on the broad and apparently neutral and culture-free documentation of 'difference' and 'variation,' they usually separated 'us' from 'them,' expressing ethnocentric concerns with race and purity (Marks, 2008). A series of theoretical and technical innovations during the second half of the twentieth century, in particular the discovery of the double helix, allowed geneticists and scholars in related fields to finally explore the contours and structures of genetic material, to 'voyage' into the 'universe within,' in the language of the Human Genome Project in 2000. These developments, sometimes identified as the 'new genetics' (Palsson, 2007), have redefined the conceptual landscape and biometrics of human difference. Genotypic differences seem not to correspond or submit to earlier framings of phenotypic differences and classifications. Many biological anthropologists, in fact, have sought to change popular understandings of race, emphasizing that race has no biological basis. This does not, however, rule out the possibility of somehow reintroducing earlier categorizations of races under the modern labels of genotypes, populations, and ethnic groups.

Background

National collections and databases of the kind discussed here draw upon a series of developments in the history of states and bureaucracies, including practices of writing, accounting, and monitoring represented by 'statistics of sickness.' Thus, in nineteenth-century England the medieval documentation that traditionally had focused on births, deaths, and marriages was extended to statistics and probabilistic methods to describe the health risks and tendencies of the population and its subdivisions: "Disease, madness, and the state of the threatening underworld, *les misérables*, created a morbid and fearful fascination for numbers upon which the bureaucracies fed" (Hacking, 1982: p. 287). Developed in one nation state after another, such statistics represented biopolitical concerns with monitoring and governing the health of the national body and the national population. While this new 'avalanche in numbers,' Hacking suggests, was rarely efficient in managing the population of study, it had subversive effects, namely "to create new categories into which people had to fall, and so to create and to render rigid new conceptualizations of the human being" (1982: 281). Keeping in mind that the term 'nation' is etymologically derived from *nascere* (to be born), health statistics, in a sense, establish the birthmarks of the national body.

At the beginning of this century, a series of biomedical projects normally described as 'biobanks' were developed in different parts of the world. Drawing upon the scientific perspectives of the new genetics and the politics of neoliberal governance, such projects were usually designed and developed as *national* projects, focusing on national populations, health statistics, and lifestyles. These biomedical innovations are not just innovative technical, scientific, and economic enterprises; they are radical experiments in biopolitics with potentially diverse social implications for individuals, families, communities, and the public at large. The broad responses to such experiments, however, vary from one case to another.

The History of 'Human Variation'

For a long time, the study of human bones was an important component of physical anthropological and archaeological research on human variation and history. Skulls in particular were endlessly recovered from graves, measured, classified, analyzed, stored, and displayed in museums and archives. With its set of tools for measuring human bodies, from the 'anthropometron' of the seventeenth century and the 'craniometer' of the nineteenth century onward, physical anthropology carried an aura of objectivity and precision, of proper science. It helped, too, that rules were drawn up for the

standardizing of anthropological measurements, at the International Congress of Anthropology in Monaco in 1906 and in Geneva in 1912. Perhaps this hammered home the point that racial classifications and national typologies were somehow engraved in the biological world, and not imposed by the spectator.

Passionate bone collection and measurements continued in some contexts throughout the twentieth century, both constituting and being constituted by the imagined communities (cf. Anderson, 1983) of nations, cultures, and disciplines and their traditions of remembrance and authority (Connerton, 1989). As Verdery (1999: 27) notes, because bones are material things and 'indisputably there,' they have political lives of their own: "A body's materiality can be critical to its symbolic efficacy." Hooton's (1931) influential work *Up from the Apes*, originally published in 1931, discussed the 'blood stream of the human races,' comparing the history of races with the circulatory system. The blood ties assumed by Hooton clearly reflected his own racist ideas. Nordic peoples were, for instance, according to him, both fairly pure races and near the forefront in human development, while bringing up the rear were 'Arctic Mongoloids.' Commenting on race, Hooton suggested that "confusions of usage are usually confined to the non-anthropological writing public. All anthropologists agree that the criteria of race are physical characteristics" (Hooton, 1946: 447). For Hooton, skeletal material was the main source of information on human variability and national types. The measurement and classification of bones became an obsession. This is underlined by the extensive cross-cultural bone collections of the Peabody Museum at Harvard University, which are stored in hundreds of cardboard boxes in a large hall of the museum and labeled with the names of nations, peoples, and places.

Saturated with listings and descriptive statistics, the massive catalogs often produced by physical anthropologists provide a useful clue to the 'problem orientation' of their time: "amass enough data and problems will sort themselves out" (Scott et al. 2000: p. 347). Often devoid of theory and focusing on preconceived human types, passionate skeletal studies and catalogs continued in some contexts throughout the twentieth century. Sometimes the goal was partly to understand particular medical conditions evident in skeletal structures of particular populations.

Modern genetics was born at the beginning of the twentieth century with the rediscovery of Mendel's laws of inheritance. By the middle of the century, a series of critical developments revealed the molecular mechanisms of inheritance. Twentieth-century advances in cell research also made it possible to extract, store, and manipulate cellular material outside the host organism. With the 'modern evolutionary synthesis' of the 1940s and the 'new genetics' of the 1960s onward, biological anthropology took off. It was not until the 1990s, however, that DNA gradually began to replace skeletal material and other sources (texts, languages, and archaeological remains) as the avenue into human history and variation. A few geneticists and biological anthropologists began to see bones as almost trivial antiques (see Sommer, 2008), somewhat like ancient manuscripts, secondary to DNA sequences and gene frequencies. At the same time, genomics acquired a central place in national projects, as a powerful avenue into health and history. Keeping in mind, however, that formerly discarded sources of data sometimes acquire new meaning as a result of conceptual and methodological advances, skeletal morphology should not be discounted.

Intensive genetic research over recent decades has revealed what are usually seen as the biologically encoded instructions necessary for constructing and maintaining a living example of an organism. What people make of this in different contexts, however, is an important ethnographic question. One form of current gene talk assumes that genetic makeup largely accounts for individual development and characteristics. Along with biotechnological advancements, such a perspective has led to the escalation of research on the genes assumed to be implicated in human diseases. A related development is 'biobanking,' the assembly of a variety of medical and genetic information on specific populations, for the purpose of advancing the industrial development of medical remedies. Anthropologists and other social scientists have studied several aspects of these developments, particularly their implications for biopolitics and the construction of genetic citizenship, notions of belonging informed by genetic theory and practice (Rapp et al., 2001).

Biobanks

Cambon-Thomsen (2004: p. 866) refers to 'biobanks' as 'organized collections of biological samples and data associated with them,' one subset of which is 'population biobanks.' Such a definition is no longer exact as many databases now do not contain actual biological samples, being restricted to numeric representations of molecular properties. Since the biobank concept is rather broad and fuzzy, several others have been suggested for the kind of large-scale biomedical assemblies employed by the new genetics, including 'genetic databases,' 'biomedical collections,' 'population biomedical collections,' 'genebanks,' and 'biothèques' or 'biolibraries.' Tutton and Corrigan (2004: 3) see 'genetic databases' as "involving the collection, storage and use of physical tissue (usually blood, but by no means exclusively), genotype and other biological information derived from that tissue, and a variety of personal data from populations of various sizes." In such a definition, a genetic database typically combines (temporarily at least) two kinds of banking, one corporeal (DNA samples) and another informational (including medical records). A number of national or regional genetic database projects and proposals have been discussed in a variety of contexts since the 1990s – in Iceland, Tonga, Sweden, the United Kingdom, Estonia, Québec, Taiwan, Germany, Israel, Japan, Latvia, Newfoundland, Norway, Sardinia, Singapore, and the United States – with concerns with nationhood, health, monitoring, research, and commercialization, revealing at the same time different scales and designs (Palsson, 2007; Gottweis and Peterson, 2008).

Some database projects involve tiny and rather homogeneous island populations, others are set up for 'ethnic' regions, and still others cover huge and complex populations, potentially a substantial part of humanity. Apart from differences in the scale of the populations involved, database projects differ with respect to the processes and criteria of sampling, property

arrangements and management regimes, the nature and degree of commercial involvement, forms of consent, as well as measures for the protection of personal information. There are important similarities as well. All contexts represent a concern with the governing of bodies, populations, and welfare, monitoring the health of the national or ethnic body. One of the implications of this monitoring is the geneticization of notions of citizenship and belonging. DNA signatures not only specify who belongs to the nation or the ethnic community, who is entitled to the relevant privileges and who is not (the privileged rights to casino profits, for instance, in some indigenous North American contexts), but also help to establish new biosocialities along genetic lines, real or virtual communities based on shared characteristics or conditions (breast cancer, arthritis, etc.). This development is accelerated by digital genealogies, globalization, and network society.

The National and the Transnational

In 1998, the Icelandic Parliament passed a bill authorizing the construction of a Health Sector Database. In doing so, it launched a 'genome biobank boom' (Hinterberger, 2012), a new concept in biomedicine that has had a significant impact on biomedicine in many national contexts. The license to construct the database was open to competition; the licensee would finance it, and the resulting assembly would belong to the National Health Service, with the licensee retaining privileged rights to commercialize it for 12 years. Eventually, a company called deCODE genetics, Inc. was granted the license to construct the database. The text for the license specified that the company should pay the Icelandic state a certain fee for the assembly and use of the records of the medical service. For the spokespersons of the database, the power of genetic and epidemiological analyses would be greatly enhanced. The medical records available since 1915, it was argued, would allow for the exploration of a set of new questions on the interaction among a number of variables apart from genetic makeup and genealogical connections, including variables pertaining to lifestyle, physical and social environments, the use of particular medicine, and degree and kind of hospitalization.

The project seemed plausible and scientifically promising because the Icelandic population has been small, relatively homogeneous, and comparatively isolated. Such populations, it was argued, would simplify and speed up the hunting for mutant genes potentially responsible for common diseases. It also helped that Icelanders have had a passion for keeping genealogical records, facilitating analyses of genetic distance and correlations between genotypes and health. A relatively homogeneous population with good genealogical as well as medical records (for precise phenotypic identification of symptoms), it was argued, was the ideal experimental site for biomedical analysis. According to deCODE genetics and their investors, Icelanders met such conditions better than most other populations. Similar arguments were advanced in some other contexts, although some maintained that larger and more heterogeneous populations were better for such purposes. From the point of view of members of the Icelandic Parliament, ministers and representatives of the state, the Health Sector Database would render the health care system more efficient, making it possible to monitor the impact of drugs, health care, and the role of lifestyle. The results might be useful for pharmaceutical companies and for the medical service, producing information on potential drugs, particular genes or proteins, and possible preventive measures in terms of consumption and lifestyle. From the point of view of deCODE genetics, a database would speed up the search for genes responsible for common diseases and the development and manufacture of 'personalized' drugs. As Winickoff (2006: p. 97) observes, the Icelandic Health Sector Database became an experimental site for genomics and genomic governance in the sense that it "helped produce the technological, political, and normative terrain of all large-scale genomics initiatives today, not just Iceland's."

Another illuminating case is the Canadian project Cart@gène focusing on Québec. The plan was to approach 90 000 people aged between 25 and 74 years, randomly selected from medical records (Hinterberger, 2012). It was hoped that two-thirds of those approached would respond positively and serve as the foundation of the database through their biological samples. The participants would then respond to questionnaires about family history and health profile and donate blood for DNA analysis. The Cart@gène project is a joint venture of the Balsac project of the University of Québec, research institutes at McGill University, and the Faculty of Law at the University of Montréal. The aim is similar to that of the deCODE project – to map the local genomes, to throw light on the 'predispositions' of particular groups for developing certain diseases (e.g., hypertension, diabetes, asthma, and cancer), to explore the relationship between genetic characteristics and environmental variables, and to establish the local economy as an important site in the globally emerging genomic research (Bibeau, 2004).

During the planning process, important changes were made to the original outlines, partly as a result of debates on the relative roles of the state and private companies. For one thing, information entered into the bank would remain anonymous. Eventually, the project was defined as a 'population' health survey, a nonprofit enterprise with no specific commercial involvement. Bibeau (2004: 100) suggests that despite differences with respect to commercial involvement, the contexts of Québec and Iceland have much in common, in terms of public confidence in researchers, the progress of medicine, attitudes toward the pharmaceutical industry, and support to public health care services. Last but not least, Québec and Iceland share the scientific advantages provided by great interest among the public in family histories. About 10 000 French immigrants settled in 'New France' in Québec between 1608 and 1760 and, apparently, many people in Québec can trace their roots back 10 or even 15 generations. The success of modern genealogy companies can be partly explained by the desire of the descendants of the pioneers to trace their roots to a particular region in France and, obviously, the Cart@gène project benefits from this interest in roots. Bibeau (2004: 120) suggests, however, that the Québec genome has never been 'homogeneous' and that the true reason for interest among academics and industry in genome research, irrespective of the rhetoric of roots, has to do with the fact that Québec has demographic files and genealogical information 'without a doubt more complete

than those in Iceland and just as rich in information as the genealogical sources of the Mormons in Utah.'

Emerging in many contexts throughout the world, communities of relatedness based on genetic testing represent a revitalization of biological metaphors to mark belonging beyond established political boundaries, signaling the growth of what Glick Schiller (2005) calls 'long-distance nationalism.' Significantly, the Canadian Cart@gène project has partnered with a genealogical project in Québec (Balsac), a population register in a computerized database established for tracking family histories of French Canadians (Hinterberger, 2012). Such partnership seems geared to nourishing long-distance French nationalism, the imagined community of descendants of the 'Québec founder population' and their European ancestors, across national boundaries. Transnational political projects to build a state or an ethnic community thus increasingly draw upon notions of biological belonging informed by genetic testing. Israel is a case in point (Prainsack and Hashiloni-Dolev, 2009).

Despite the national or regional rhetoric of many database projects, there is much formal and informal collaboration among them. Recently, L. L. Cavalli-Sforza, one of the pioneers of the Human Genome Diversity Project, has suggested that national genetic databases might contribute to the project's collection by donating blood samples, 'representing a minute fraction of their collection, ideally forming a geographically (and if necessary, linguistically and ethnically) stratified sample of the country' (Cavalli-Sforza, 2005: 340). One of the recent territories of biomedicine is the move beyond 'national' genomes to comparative datasets such as that of the International Haplotype Map Project, drawing upon the power of genome-wide scans and related technological and methodological advances. Drawing upon its comparative tool kits, anthropology has often been involved in such projects, sometimes as a key player (Palsson, 2008). Quite possibly in the future, large-scale genetic and genomic databases will be operative at numerous sites, either permanently or from time to time. For gaining larger numbers and samples, which may be important for analyzing many common diseases, different database projects may find it feasible to temporarily share data, hunting and gathering in the human genome on an unprecedented scale under some kind of permanent institutional umbrella.

Genealogies and Ancestry

Iceland's Health Sector Database project collapsed for several reasons, including financial, ethical, and legal ones. While the project failed to materialize, it had several spin-offs, including the development of flexible, interdisciplinary research teams; powerful genomic laboratories; bioinformatic frameworks; the personal genomics of deCODEme (Palsson, 2012); and, last but not least, the Book of Icelanders, a genealogical database that lists the majority of the total number of people ever born in Iceland. The point is not simply to record individuals but rather to be able to connect them to each other. deCODE genetic's chief aim by the construction of the Book of Icelanders was to advance genetic and biomedical research. One of its two versions is available only to deCODE researchers. In this case, no names are included, only numbers or IDs that allow for the combination of different datasets on a limited basis for particular research purposes.

Some of the imagery of the Book of Icelanders and the deCODE project can be taken as emblematic of national genomic projects in general. One of the images (Figure 1), reproduced on deCODE genetics' T-shirts and web pages, has functioned as the informal logo of the company. It shows a pedigree with 11 generations. The current-day Icelanders diagnosed with asthma (filled squares and circles in the figure) are limited to the last generation or two, but their relationships are known through 11 generations and all of them are descendants of a single founder born in the seventeenth century. Apart from its visual appeal, the circular image may serve, consciously or not, to foster a sense of unity and national belonging and a genetic notion of citizenship.

While one version of the Book of Icelanders was produced for deCODE genetics, another version has been available since 2003, free of charge, on the Internet (http://www.islendingabok.is). This version, of course, has no encryption. It enables 'Icelanders' to trace their family histories and to explore their genealogical connection to almost any Icelander living or dead. The responses to the genealogies on the web were overwhelming. Overnight, the Book of Icelanders became a popular pastime. In a few weeks, 100 000 Icelanders, about one-third of the total population, requested a password, exploring their relations with neighbors, colleagues, and friends. Soon the database became a party game. Recently, the Book of Icelanders was linked to Facebook, illustrating some of the connections between genomics, genealogies, and network society.

Increasingly, family histories are explored and celebrated on the web by the curious and enthusiastic public. Thus, in the United Kingdom several websites – including Ancestry.co.uk,

Figure 1 An asthma-pedigree with 11 generations. Source: deCODE genetics.

Genes Reunited, 1837online.com, and Achievements.co.uk – offer a range of genealogical services, either free of charge or for a certain fee. Some allow for the making and storing of family albums with details of family events, photos, and videos; others help users to create family trees; and still others provide access to records of births, baptism, deaths, and marriages. TV programs such as Channel 4's 'Extraordinary Ancestors' and BBC2's 'Blood Ties' testify to an extensive interest among the general public. In the United States too, there are several powerful genealogical websites, among them MyFamily.com and FamilySearch.org. The latter is run by the Church of Jesus Christ of Latter-Day Saints in Utah, drawing upon the extraordinary genealogical sources assembled by the Mormons over the years.

Many of the genealogical projects on the web are a by-product of the new genetics, combining in one fashion or another genetic and genealogical research (Tutton, 2004). The Huntsman Cancer Institute of the University of Utah has assembled life and health histories for 1.6 million Utahans, living or dead, into the Utah Population Database. 'Mormon genes are hot,' as a front-page article in the *New York Times* had it (Johnson, 2004), mainly because of the wealth of family histories but also because of the practice of polygamy in the past that has amplified the genetic imprint of a relatively small number of males. Another Utah-based project is the Sorenson Molecular Genealogy Foundation. Appealing to volunteers from all over the world to participate in its project, it combines Y chromosome, mtDNA, and autosomal genetic markers with established genealogies. Thousands of people from different countries have participated in the project, providing genealogical information and donating a DNA sample taken through mouthwash. The sole purpose of this enterprise is to identify possible genealogical links on the basis of 'molecular genealogy.'

The extent to which genomic evidence informs politics of belonging and exclusion and notions of ancestry largely remains an open empirical question. This is an important avenue for social scientific and humanities scholarship. Prainsack and Hashiloni-Dolev (2009) explore several cases in which genomic experts have tried to use genetics to 'verify' or 'falsify' particular group identities, including the case of genetic distance between Arabs and Jews and the 'Jewish' ancestry of the Lemba of South Africa. It turns out that the picture is more complicated than current discourses on genetic citizenship would lead one to believe and that DNA evidence need not have significant political implications.

The Future

To conclude, how will national projects and the sciences of human variation, in particular genomics and anthropology, be affected by scientific advances, conceptual change, and social developments? In her early historical account of the instruments of physical anthropology, Hoyme (1953: p. 425) had no doubts about the bright future ahead; speculating about the next 50 years, she suggested that it is "fairly certain … that anthropometry, the hallmark of physical anthropology, will be retained among the techniques of the anthropologist, although techniques from other biological sciences will undoubtedly be adopted where needed… There are many problems involving size and proportion not yet solved, and perhaps not yet suggested by genetics, physiology, ecology, and comparative anatomy, for which anthropometry can provide basic data." Yet, modern readers cannot help but wonder why people bothered with all the measurements and indices produced. Hoyme (1953: p. 423) admitted that it "is somewhat … difficult to draw conclusions as to why these measurements and indices were considered worthy of investigation," adding that "it is necessary to examine the studies against the climate of opinion of the period in which they were carried out." One of their main rationales was their role in sustaining national projects, establishing and maintaining identities and boundaries.

Just as the anthropometry of past centuries was moved from the center of national projects and studies of human variation, the focus on human genomics of recent decades is bound to change. While genomic avenues into history, difference, and relatedness have proved quite powerful, it seems likely that they, too, will be redirected. Already, a series of developments can be observed on the horizon, among them the escalation of computing power with advances in bioinformatics and computer technology facilitating complete genome sequencing at low price, the growth of personal genomics and digital networking, the federation of private and national biobanks, the growing evidence of microbiomes and epigenetic processes, and new forms of biopolitics and governance. The last two developments mentioned are probably of particular interest for shaping the future of genomics as national projects.

The discovery of the double helix by the middle of the twentieth century fostered the notion of genes as the 'secret of life.' The theoretical and analytical scope, however, has now been significantly broadened. Not only has the failure to make significant medical predictions on the basis of single genes increasingly drawn attention to multigenic studies assuming complex interaction and articulation, but also the stability of the genome has been seriously questioned. While the genome has largely been seen as 'an ensemble of genes strung along the chromosomes' (Barnes and Dupré, 2008: 76) with identical copies in every cell, it now seems that the dogma that all the cells of an individual are identical in terms of DNA needs rethinking. If it turns out that human genomes are unstable and variable assemblies, it becomes increasingly difficult to sustain claims about authentic or 'real' genomes, whether individual or national.

The fact that what is normally considered the 'human' genome is fundamentally mixed with the microbiomes of other organisms further complicates the picture. The human body, it turns out, is a kind of supraorganism carrying with it trillions of microbes constituting about 99% of its genes. The spokespersons for the so-called Human Microbiome Project (Turnbaugh et al., 2007) anticipate the establishment of microbial observatories worldwide for the purpose of mapping diversity and for linking microbiomes to the planetary environment. The evidence already accumulated necessarily destabilizes the issue of human variation and national genomes. If recent excursions into the human genome have been fixated on the 'wrong' genes, or at least a tiny set, and humans are best seen as supraorganisms, will 'human' genomics and genomic anthropology, in the traditional sense, be relegated to history as

trivial, narrow-minded exercises? What could possibly be 'national' in mapping the genomes of trillions of bugs in our guts and exploring their implications for our health – and who would bother to engage in their study?

In fact, this is a thriving field already. Alternatively one might ask, assuming growing public awareness of the role of microorganisms for health and development, will human genomics 'simply' become more complicated, casting its nets much wider than before and vastly expanding its range? The latter scenario, it seems, would call for enhanced governance concerns, emphasizing contexts of both community and environment. It seems likely, too, that casting the genomic net more widely to incorporate the vast terrain of microbiomes is bound to radically change current notions of human variation. The tentative results of this trend, sometimes called the 'microbiome revolution,' seem to indicate a clustering of human supraorganisms that does not correlate with classical categorizations based on 'race,' color, morphology, and continental background. To what extent and how they will affect national projects and imagined communities remain to be seen.

Moving beyond genes and genomes, organisms are partly regulated through a host of environmental forces that leave their mark on their genomes. The results of a number of recent studies suggest that for humans, early environments condition the possibility for gene expression, potentially affecting health and well-being. Such 'epigenetic' regulation seems to be prevalent in the human genome. Epigenetic 'imprints' are not changes in genetic sequence, but their effects are nevertheless 'memorized' and passed on as inheritance (Landecker, 2011). To account for the growing awareness of nongenetic factors, new terms have been entering biology and related fields, such as epigenome, methylome, and interacteome. While the notion of 'epigenetics' is used in different fashions among biologists, social scientists, and humanities scholars, this should not confuse here. 'Biology,' in any case, is a far more fleeting and complex phenomenon than normally imagined. The notion of 'national genomes' begins to look incredibly unstable and messy, if not meaningless. What bodily signatures, if any, one may ask, will replace those of genomes in the national projects of the future?

One driving force behind the growing governance discourse of the late twentieth century was the advancement in many contexts of the 'new economy' and free-market, neoliberal movements and governments, highlighted by the theorizing of Friedrich Hayek and the politics of Ronald Reagan and Margaret Thatcher. This was the discourse that partly drove the development of national biobanks and related developments, many of which were the private initiatives of multinational start-up companies. Much debate on bioethics and biopolitics focused on how to regulate the activities of biotech companies and the free-market through national machinery. In general, the rapidly expanding discourse on bioethics tended to apply highly individualistic notions of privacy and autonomy, including the notion of informed consent. Much indicates that this discourse is undergoing significant change. In some instances, research institutions utilizing a person's DNA are seen as custodians, stewards, or trustees (Winickoff and Winickoff, 2003) of genetic information, underlying the language of 'benefit sharing' and the 'Common Heritage' of international law. Indeed, governance models alternative to those of the individual, the market, and the state seem to be needed for dealing with the embedded person or body. A recent report on 'Solidarity' (Prainsack and Buyx, 2011) published by the Nuffield Council on Bioethics is one significant step forward in the direction of collective governance, outlining the history of the concept of solidarity and related terms, their growing salience in political theory and public discourse, and their usefulness in the context of concerns with pandemics, lifestyle-related diseases, and national biobanks.

Abstract

Anthropology, the study of humanity seen from the perspective of social and cultural diversity, was established as an academic discipline in the mid-nineteenth century. At the time, broad, evolutionist perspectives were predominant, but would be eclipsed in the early twentieth century by the cultural relativism introduced by Franz Boas and the fieldwork revolution championed by Bronislaw Malinowski. During the twentieth century, anthropology became a diverse pursuit ranging from intensive functionalist studies of small-scale societies to ambitious modeling of the human mind, interpretive approaches and ecological accounts. Toward the end of the century, Marxist, feminist, and postcolonial critiques led to a heightened sensitivity toward methodological and ethical issues, and a major preoccupation in the early twenty-first century has consisted in accounting for the impact of globalization on local communities. In this intensely interconnected world, where formerly influential theoretical paradigms have collapsed, anthropology remains committed to comparison and ethnographic fieldwork, applying methods initially developed to study tribal society to research on complex societies.

Early attempts at accounting for cultural variation and human universals, the subject matter of anthropology, include ancient Greek geography and history, Renaissance and early modern travelogues, and philosophical treatises from the European Enlightenment. They fell short of being scientific because of inherent bias, lack of theoretical sophistication, and, frequently, poor empirical material. In the nineteenth century, theorists such as Henry Lewis Morgan, Henry Maine, and Edward Tylor developed ambitious evolutionist theories of culture, implying a hierarchical view of cultures. Modern anthropology emerged in the early decades of the twentieth century, when a new generation of scholars, notably Franz Boas, A.R. Radcliffe-Brown, Bronislaw Malinowski, and Marcel Mauss, rejected evolutionism replacing it with cultural relativism, also refining research methodologies and methods of comparison. In the decades following World War II, new approaches such as structuralism, cultural ecology, and neo-Marxism appeared, and anthropology grew and diversified, branching into various specializations including psychological and medical anthropology, eventually moving increasingly toward the study of modern phenomena such as nationalism and consumption, yet retaining its commitment to the intensive, fieldwork-based study of social life in local settings.

Social or cultural anthropology can be defined, loosely and broadly, as the comparative science of culture and society, and it is the only major discipline in the social sciences that has concentrated most of its attention on non-Western people. Although many of the classic problems investigated by anthropologists are familiar to the European history of ideas, the subject as it is known today emerged only in the early twentieth century, became institutionalized at universities in the Western world in midcentury, and underwent a phenomenal growth and diversification in the latter half of the century.

Foundations and Early Schools

Proto-Anthropology

Interest in cultural variation and human universals can be found as far back in history as the Greek city-state. The historian Herodotos (fifth century BC) wrote accounts of 'barbarian' peoples to the east and north of the peninsula, comparing their customs and beliefs to those of Athens, and the group of philosophers known as the Sophists were perhaps the first philosophical relativists, arguing (as many twentieth-century anthropologists later did) that there can be no absolute truth because, as one would put it today, truth is contextual. Yet their interest in cultural variation fell short of being scientific, chiefly because Herodotos lacked theory while the Sophists lacked empirical material.

Centuries later, scholarly interest in cultural variation and human nature reemerged in Europe because of the new intellectual freedom of the Renaissance and questions arising from European overseas exploits. Michel de Montaigne (sixteenth century), Thomas Hobbes (seventeenth century), and Giambattista Vico (eighteenth century) were among the thinkers of the early modern era who tried to account for cultural variability and global cultural history as well as dealing with the challenge from relativism. Eighteenth-century philosophers such as Locke, Hume, Kant, Montesquieu, and Rousseau developed theories of human nature, moral philosophies, and social theories, taking into account an awareness of cultural differences. The early German romantic Herder challenged Voltaire's universalistic vision by arguing that each people (*Volk*) had a right to retaining its own, unique values and customs – in a manner reminiscent of later cultural relativism romanticism. Indeed, by the end of the eighteenth century, several of the general questions still raised by anthropologists had already been raised: Universalism vs relativism (what is common to humanity; what is culturally specific), ethnocentrism vs cultural relativism (moral judgments vs neutral descriptions of other peoples), and humanity vs the rest of the animal kingdom (culture vs nature). Twentieth-century anthropology has taught that these and other essentially philosophical problems are best investigated through the detailed study of living people in existing societies through ethnographic fieldwork, and by applying carefully devised methods of comparison to the bewildering variety of 'customs and beliefs.' It would take several generations after Montesquieu's comparative musings about Persia and France,

in his *Lettres persanes*, before anthropology achieved this mark of scientific endeavor.

Victorian Anthropology

The first general theories of cultural variation to enjoy a lasting influence were arguably those of two men trained as lawyers: Henry Maine (1822–88) in Britain and Lewis Henry Morgan (1818–82) in the United States. Both presented evolutionist models of variation and change, where Western European societies were seen as the pinnacle of human development. In his *Ancient Law* (1861), Maine distinguished between *status* and *contract* societies, a divide which corresponds roughly to later dichotomies between traditional and modern societies, or, in the late nineteenth-century German sociologist Ferdinand Tönnies' terminology, *Gemeinschaft* (community) and *Gesellschaft* (society); status societies are assumed to operate on the basis of kinship and myth, while individual merit and achievement are decisive in contract societies. Although simple contrasts of this kind have regularly been severely criticized, they continue to exert a certain influence on anthropological thinking.

Morgan's contributions to anthropology were wide ranging and, among other things, he wrote a detailed ethnography of the Iroquois. His evolutionary scheme, presented in *Ancient Society* (1877), which influenced Marx and Engels, distinguished between seven stages (from lower savagery to civilization). His materialist account of cultural change influenced Marx and Engels. His pioneering work on kinship divided kinship systems into a limited number of types, and saw kinship terminology as a key to understanding society. Writing in the same period, the historian of religion Robertson Smith and the lawyer J.J. Bachofen offered, respectively, theories of monotheistic religion and of the (wrongly assumed) historical transition from matriliny to patriliny.

An untypical scholar in the otherwise evolutionist Victorian era, the German ethnologist Adolf Bastian (1826–1905) reacted against simplistic typological schemata. Drawing inspiration from Herderian romanticism and the humanistic tradition in German academia, Bastian wrote prolifically on cultural history, avoiding unwarranted generalizations, yet he held that all humans have the same pattern of thinking, thus anticipating structuralism.

The leading British anthropologist of the late Victorian era was Edward Tylor (1832–1917), whose writings include a famous definition of culture (dating from 1871), seeing it as the sum total of collective human achievements (thus contrasting it to nature). Tylor's student James Frazer (1854–1941) published the massive and very influential *Golden Bough* (1890, rev. ed. 1911–15), an ambitious comparative study of myth and religion.

Intellectual developments outside anthropology in the second half of the nineteenth century also had a powerful impact. Charles Darwin's theory of natural selection, first presented in his *Origin of Species* from 1859, would both be seen as a condition for anthropology (positing that all humans are closely related) and, later, as a threat to it (arguing the primacy of the biological over the cultural). The emergence of classic sociological theory in the works of Comte, Marx, and Tönnies, and later Durkheim, Weber, Pareto, and Simmel, provided anthropologists with general theories of society, although their applicability to non-European societies continues to be disputed (*see* Sociology, History of).

The quality of the data used by the early anthropologists was variable. Most of them relied on written sources, ranging from missionaries' accounts to travelogues of varying accuracy. The need for more reliable data began to make itself felt. Expeditions and systematic surveys now provided researchers around the turn of the twentieth century with improved knowledge of cultural variation, which eventually led to the downfall of the ambitious theories of unilineal evolution characteristic of nineteenth-century anthropology.

An Austro-German specialty proposed both as an alternative and a complement to evolutionist thinking was diffusionism, the doctrine of the historical diffusion of cultural traits. Never a part of the mainstream outside of the German-speaking world, elaborate theories of cultural diffusion continued to thrive, particularly in Berlin and Vienna, until after World War II (Gingrich, 2005). As there were serious problems of verification associated with the theory, it was condemned as speculative by anthropologists committed to fieldwork and, furthermore, research priorities were to shift from general cultural history to intensive studies of particular societies.

In spite of theoretical developments and methodological refinements, the emergence of anthropology, as the discipline is known today, is rightly associated with four scholars working in three countries in the early decades of the twentieth century: Franz Boas in the United States, A.R. Radcliffe-Brown and Bronislaw Malinowski in the United Kingdom, and Marcel Mauss in France.

Boas and Cultural Relativism

Boas (1858–1942), a German migrant to the United States, who had briefly studied anthropology with Bastian, carried out research among Eskimos and Kwakiutl Indians in the 1890s. In his teaching and professional leadership, he strengthened the 'four-field approach' in American anthropology, which still sets it apart from European anthropology, including both cultural and social anthropology, physical anthropology, archaeology, and linguistics. Although cultural relativism had been introduced more than a century before, it was Boas who made it a central premise for anthropological research. Against the evolutionists, he argued that each culture had to be understood in its own terms and that it would be scientifically misleading to rank other cultures according to a Western, ethnocentric typology gauging 'levels of development.' Boas also promoted *historical particularism*, the view that all societies or cultures had a unique history that could not be reduced to a category in some universalistic scheme. On related grounds, Boas argued incessantly against the claims of *racist* views of human diversity.

Perhaps because of his particularism, Boas never systematized his ideas in a theoretical treatise. Several of his students and associates nevertheless did develop general theories of culture, notably Ruth Benedict, Alfred Kroeber, and Robert Lowie. His most famous student was Margaret Mead (1901–78). Although her best-selling books on Pacific societies have been criticized for being superficial, she used material from non-Western societies to raise questions about gender

relations, socialization, and politics in the West, and Mead's work indicates the potential of cultural criticism inherent in the discipline.

One of Boas' most remarkable associates, the linguist Edward Sapir (1884–1939), formulated, with his student Benjamin Lee Whorf, the Sapir–Whorf hypothesis, which posits that language determines cognition. Consistent with a radical cultural relativism, the hypothesis implies that, for example, the Hopi perceive the world in a fundamentally different way from Westerners, due to differences in the structure of their respective languages. A controversial perspective from the beginning, the hypothesis has nonetheless continued to be discussed in linguistics and linguistic anthropology.

The Two British Schools

While modern American anthropology had been shaped by the Boasians and their relativist concerns, as well as the perceived need to record native cultures before their anticipated disappearance, the situation in the major colonial power, Great Britain, was different. The degree of complicity between colonial agencies and anthropologists is debatable, but the very fact of imperialism was an inescapable premise for British anthropology until after World War II.

The man who is often hailed as the founder of modern British social anthropology was a Polish immigrant, Bronislaw Malinowski (1884–1942), whose fieldwork for over 2 years in the Trobriand Islands (1914–18) set a standard for ethnographic data collection that is still largely unchallenged. Malinowski argued the need to learn the local language properly and to engage in everyday life, in order to see the world from the actor's point of view and to understand the interconnections between social institutions and cultural notions. Malinowski placed an unusual emphasis on the acting individual, seeing social structure not as a determinant of but as a framework for action, and he wrote about a wide range of topics, from garden magic, economics, and sex to the puzzling *kula* trade. Although he dealt with issues of general concern, he nearly always took his point of departure in his Trobriand ethnography, demonstrating a method of generalization very different from that of the previous generation with its scant local knowledge.

The other major British anthropologist of the time was A.R. Radcliffe-Brown (1881–1955). An admirer of Durkheim's sociology, Radcliffe-Brown did relatively little fieldwork himself, but aimed at the development of a 'natural science of society' where universal laws of social life could be formulated. His theory, known as structural functionalism, saw the individual as unimportant, emphasizing instead the social institutions (kinship, norms, politics, etc.). Most social and cultural phenomena were seen as functional in the sense that they contributed to the maintenance of the overall social structure (*see* Functionalism in Anthropology).

Despite their differences in emphasis, both British schools had a sociological concern in common (which they did not share with most Americans), and tended to see social institutions as functionally integrative. Both rejected the wide-ranging claims of diffusionism and evolutionism, and yet, the tension between structural explanations and actor-centered accounts remains strong in British anthropology even today.

Malinowski's students included Raymond Firth, Audrey Richards, and Isaac Schapera, while Radcliffe-Brown, in addition to enlisting E.E. Evans-Pritchard and Meyer Fortes – arguably the most powerful British anthropologists in the 1950s – on his side, taught widely, and introduced structural functionalism to several foreign universities. British interwar anthropology was characteristically oriented toward kinship, politics, and economics, with Evans-Pritchard's masterpiece *The Nuer* (1940) demonstrating the intellectual power of a discipline combining detailed ethnography, comparison, and elegant models. Later, his models would be criticized for being too elegant to fit the facts on the ground – a very Malinowskian objection.

Mauss

No fieldwork-based anthropology developed in the German-speaking region, and German anthropology was marginalized after World War II. In France, the situation was different. Already in 1902, Durkheim had published, with his nephew Marcel Mauss (1872–1950), an important treatise on primitive classification; in 1908, Arnold van Gennep published *Les Rites de Passage*, an important analysis of initiation rites, and Lucien Lévy-Bruhl elucidated a theory, later refuted by both Evans-Pritchard, Mauss, and others, on the 'primitive mind,' which he held to be 'prelogical.' New empirical material of high quality was being produced by thorough observers such as Maurice Leenhardt in New Caledonia and Marcel Griaule in West Africa.

Less methodologically purist than the emerging British traditions and more philosophically adventurous than the Americans, interwar French anthropology, under the leadership of Mauss, developed a distinct flavor, witnessed in the influential journal *L'Année Sociologique*, founded by Durkheim and edited by Mauss after Durkheim's death in 1917. Drawing on his vast knowledge of languages, cultural history, and ethnography, Mauss, who never did fieldwork himself, wrote several learned, original, compact essays ranging from gift exchange (*Essai sur le Don*, 1924) to the nation, the body, and the concept of the person. Mauss' theoretical position was complex. He believed in systematic comparison and the existence of recurrent patterns in social life at all times and in all places, yet he often defended relativist views in his reasoning about similarities and differences between societies.

Not a prolific writer, Mauss exerted an enormous influence on later French anthropology through his teaching. Among his students and associates were most of the major French anthropologists at the time, and the three leading postwar scholars in the field – Louis Dumont, Claude Lévi-Strauss, and Georges Balandier – were all deeply indebted to Mauss.

Some General Points

The transition from evolutionist theory and grand syntheses to more specific, detailed, and empirically founded work, in reality amounted to an intellectual revolution. The work of Tylor and Morgan had been relegated to the mists of history by the mid-twentieth century, and the discipline had been taken over by small groups of scholars who saw intensive fieldwork, cultural relativism, the study of single societies, and rigorous

comparison as its essence. Today, the academic institutions, the conferences, and the learned journals all build on the anthropology of Boas, Malinowski, Radcliffe-Brown, and Mauss. This is to a great extent also true of the anthropological traditions of other countries (Vermeulen and Roldán, 1995), including India, Australia, Mexico, Argentina, the Netherlands, Spain, and Scandinavia. Soviet/Russian and East European anthropologies have followed different itineraries, retaining a connection with the German tradition, where *Volkskunde* (ethnology, studies of rural folk culture in one's own society) was distinguished from *Völkerkunde* (literally the study of peoples, that is other cultures). In Russia, there had existed a rich tradition of empirically based anthropological research since the early nineteenth century, and twentieth century Soviet anthropology combined *Völkerkunde* and Marxist influence in original ways (see Eriksen and Nielsen, 2012), but there was little contact with the Western mainstream until the end of Communism (but see Gellner, 1980).

Anthropology in the Second Half of the Twentieth Century

The numbers of anthropologists and institutions devoted to teaching and research in the field grew rapidly after World War II. The discipline diversified. New specializations such as psychological anthropology, political anthropology, and the anthropology of ritual emerged, and the geographical foci of the discipline multiplied: whereas the Pacific had been the most fertile area for theoretical developments in the 1920s, and Africa had played a similar part in the 1930s and 1940s, while the preoccupation with North American Indians had been stable throughout, the 1950s saw a growing interest in the 'hybrid' societies of Latin America and the Caribbean as well as the anthropology of India and South-East Asia, and the New Guinean highlands became similarly important in the 1960s. Such shifts in spatial emphasis had consequences for theoretical developments, as each region posed its own peculiar problems.

From the 1950s, the end of colonialism also affected anthropology, both in a banal sense – it became more difficult to obtain research permits – and more profoundly, as the subject–object relationship between the observer and the observed became problematic as the traditionally 'observed' peoples increasingly had their own intellectuals and spokespersons who frequently objected to Western interpretations of their way of life.

Structuralism

The first major theory to emerge after World War II was Claude Lévi-Strauss' structuralism. Lévi-Strauss (1908–2009) developed an original theory of the human mind, drawing on structural linguistics, Mauss' theory of exchange, and Lévy-Bruhl's theory of the primitive mind (which Lévi-Strauss opposed). His first major work, *Les Structures Elémentaires de la Parenté* (*The Elementary Structures of Kinship*, 1949), introduced a grammatical, formal way of thinking about kinship, with particular reference to systems of marriage (the exchange of women between groups). Lévi-Strauss later expanded his theory to cover totemism, myth, and art. Never uncontroversial, structuralism had an enormous impact on French intellectual life far beyond the confines of anthropology. In the English-speaking world, the reception of structuralism was delayed, as Lévi-Strauss' major works were not translated until the 1960s, but he had his admirers and detractors from the beginning. Structuralism was criticized for being untestable, positing as it did certain unprovable and unfalsifiable properties of the human mind (most famously the propensity to think in terms of contrasts or binary oppositions), but many saw Lévi-Strauss' work, ultimately committed to human universals, as an immense source of inspiration in the study of symbolic systems such as knowledge and myth.

A different, and for a long time less influential, brand of structuralism was developed by Louis Dumont (1911–99), an Indianist and Sanskrit scholar who did fieldwork both in the Aryan north and the Dravidian south. Dumont, closer to Durkheim than Lévi-Strauss, argued in his major work on the Indian caste system, *Homo Hierarchicus* (1969), for a holistic perspective (as opposed to an individualistic one), claiming that Indians (and by extension, many nonmodern peoples) saw themselves not as 'free individuals' but as actors irretrievably enmeshed in a web of commitments and social relations, which in the Indian case was clearly hierarchical.

Most later, major French anthropologists have been associated with Lévi-Strauss, Dumont, or Balandier, the Africanist whose work in political anthropology simultaneously bridged gaps between France and the Anglo-Saxon world and inspired both neo-Marxist research and applied anthropology devoted to development.

Reactions to Structural Functionalism

In Britain and her colonies, the structural functionalism now associated chiefly with Evans-Pritchard and Fortes was under pressure after the war. Indeed, Evans-Pritchard himself repudiated his former views in 1949, arguing that the search for 'natural laws of society' had been shown to be futile and that anthropology should fashion itself as a humanities discipline rather than a natural science. Retrospectively, this statement has often been quoted as marking a shift 'from function to meaning' in the discipline's priorities; Kroeber expressed similar views in the United States. Others found other paths away from what was increasingly seen as a conceptual straitjacket. Edmund R. Leach, whose *Political Systems of Highland Burma* (1954), suggested a departure from functionalist orthodoxies, notably Radcliffe-Brown's dictum that social systems tend to be in equilibrium and Malinowski's view of myths as integrating 'social charters,' would later be a promoter and critic of structuralism in Britain. Leach's contemporary Raymond Firth proposed a distinction between social structure (the statuses in society) and social organization, which he saw as the actual process of social life, whereby choice and individual whims were related to structural constraints. Later in the 1950s and 1960s, several younger social anthropologists, notably F.G. Bailey and Fredrik Barth, followed Firth's lead as well as the theory of games (a recent development in economics) in refining an actor-centered perspective on social life. Max Gluckman, a former student of Radcliffe-Brown and a close associate of Evans-Pritchard, also abandoned the strong

holist program of the structural functionalists, reconceptualizing social structure as a loose set of constraints, while emphasizing the importance of individual actors. Gluckman's colleagues included several important Africanists such as A.L. Epstein, J. Clyde Mitchell, and Elizabeth Colson. Working in southern Africa, this group pioneered urban anthropology and ethnicity studies in the 1950s and 1960s.

Neo-Evolutionism, Cultural Ecology, and Neo-Marxism

The number of anthropologists has always been larger in the United States than anywhere else, and the discipline was always diverse there. Although the influence from the Boasian cultural relativist school remains strong, other groups of scholars have also made their mark. From the late 1940s, a resurgent interest in Morgan's evolutionism led to the formulation of neo-evolutionist and materialist research programs. Julian Steward, a student of Robert Redfield (who had been a student of Radcliffe-Brown), proposed a theory of cultural dynamics distinguishing between 'the cultural core' (basic institutions such as the division of labor) and 'the rest of culture' in a way strongly reminiscent of Marx. Steward led research projects among Latin American peasants and North American Indians, encouraging a focus on the relationship between culture, technology, and the environment. Leslie White held more deterministic materialist views, but also – perhaps oddly – saw symbolic culture as a largely autonomous realm. Among the major scholars influenced by White, Marvin Harris has strengthened his materialist determinism, while Marshall D. Sahlins in the 1960s made the move from neoevolutionism to a symbolic anthropology influenced by structuralism.

Cultural ecology sprang from the teachings of Steward and White, and represented a rare collaboration between anthropology and biology. Especially in the 1960s, many such studies were carried out, including, notably, Roy Rappaport's *Pigs for the Ancestors* (1968), an attempt to account for a recurrent ritual in the New Guinean highlands in ecological terms. The upsurge of Marxist peasant research, especially in Latin America, in the 1970s, was also clearly indebted to Steward.

The appearance of radical student politics in the late 1960s, which had an impact on academia until the early 1980s, had a strong, if passing, influence on anthropology. Of the more lasting contributions, the peasant studies initiated by Steward and furthered by Eric Wolf, Sidney Mintz, and others must be mentioned, along with French attempts, represented in the very sophisticated work of Maurice Godelier and Claude Meillassoux, at synthesizing Lévi-Straussian structuralism, Althusserian Marxism, and anthropological comparison. Although Marxism and structuralism eventually became unfashionable, scholars – particularly those engaged in applied work – continue to draw inspiration from Marxist thought (*see* Field Theory).

Symbolic and Cognitive Anthropology

More true to the Boasian legacy than the materialist approaches, studies of cognition and symbolic systems developed and diversified in the United States. A leading theorist was Clifford Geertz (1926–2006), who wrote a string of influential essays advocating hermeneutics (interpretive method) in the 1960s and 1970s (*see* Hermeneutics, History of). While his originality as a theorist can be questioned, his originality as a writer is obvious, and Geertz ranks as perhaps the finest writer of contemporary anthropology. Marshall Sahlins is, with Geertz, the foremost proponent of cultural relativism today, and has published a number of important books on various subjects (from Mauss' theory of exchange to sociobiology and the death of Captain Cook), consistently stressing the autonomy of the symbolic realm, thus arguing that cultural variation cannot be explained by recourse to ecology, technology, or biology.

In Britain, too, interest in meaning, symbols, and cognition grew after the war, especially from the 1960s (partly due to the belated reception of Lévi-Strauss). British anthropology had hitherto been strongly sociological, and two important scholars who fused the legacy from structural functionalism with the study of symbols and meaning were Mary Douglas (1921–2007) and Victor Turner (1920–83). Taking his cue from van Gennep, Turner, a former associate of Gluckman, developed a complex analysis of rituals among the Ndembu of Zambia, showing their functionally integrating aspects, their meaningful aspects for the participants, and their deeper symbolic significance. Douglas, a student of Evans-Pritchard, famous for her *Purity and Danger* (1966), analyzed the human preoccupation with dirt and impurities as a way of thinking about the boundaries of society and the nature/culture divide. Prolific and original, Douglas is a major defender of a reformed structural functionalism.

Against all these (and other) perspectives regarding how 'cultures' or 'societies' perceive the world, anthropologists emphasizing the actor's point of view have argued that no two individuals see the world in the same way and that it is preposterous to generalize about societies. The impact of feminism has been decisive here. Since the 1970s, feminist anthropologists have identified often profound differences between male and female worldviews, indicating how classic accounts of 'societies' really refer to male perspectives on them as both the anthropologist and the main informants tended to be male. For example, in a restudy of Trobriand society, Annette Weiner (1976) showed that Malinowski's famous work was incomplete and ultimately misleading as he had failed to observe important social processes confined to females. Feminism also influenced anthropology by emphasizing the need for a critical reflexivity addressing the methodological and epistemological issues arising from the ethnographer's identity as, for example, a man or a woman.

Anthropology and the Contemporary World

Since the pillars of modern anthropology were erected around the World War I, the former colonies became independent, 'natives' got their own educated elites (including social scientists), economic and cultural globalization led to the spread of capitalism and consumer culture, and transcontinental migration blurred the boundaries between the traditional 'us' and 'them.' This situation entailed new challenges for anthropology that were met in various ways – revealing continuities as well as breaks with the past.

A late field to be incorporated into anthropology, but one that became the largest single area of interest from the 1970s, was the study of identity politics, notably ethnicity and nationalism. Since the publication of several important texts

around 1970 (by, inter alia, Barth and Abner Cohen in Europe, and George DeVos in the United States), anthropological ethnicity studies investigated the interrelationship between ethnic identity and ethnic politics, and explored how notions of cultural differences contribute to group identification. Since the publication of several important texts on nationalism in the early 1980s (by Ernest Gellner, Benedict Anderson, and others), this also became an important area for anthropologists. Ethnicity and nationalism are partly or wholly modern phenomena associated with the state, and thus denote a departure from the former mainstay of anthropology, the study of nonmodern small-scale societies. While ethnicity and (especially) nationalism could not be studied through participant observation only (other kinds of data are required), it was evident that anthropologists who engaged in this field remained committed to the classic tenets of the discipline; ethnographic fieldwork, comparison, and a systemic view of social reality. Also, the study of identity politics emerged as an interdisciplinary field where anthropologists, sociologists, historians, and political scientists profited from each other's expertise.

Other modern phenomena also received increased attention in anthropology from the 1970s, including consumption, 'subcultures,' wagework, and migration. The boundary between the 'Western self' and the 'non-Western other' became blurred. Anthropological studies of Western societies became common, and Europe was established as an ethnographic region along with West Africa, South Asia, and so on. Even anthropologists working in traditional settings with classic topics increasingly had to see their field as enmeshed, to a greater or lesser extent, in a global system of communication and exchange.

Because of the increased penetration of the formerly tribal world by capitalism and the state, and accompanying processes of cultural change, there was a growing demand for a reconceptualization of culture in the 1980s and 1990s, and scholars such as Ulf Hannerz and Marilyn Strathern developed fluid concepts of culture seeing it as less coherent, less bounded, and less integrated than the Boasian and Malinowskian traditions implied.

Some scholars saw the postcolonial situation as sounding the death knell of anthropology: Since the 'primitive' was gone, and the former informants were now able to identify and describe themselves (they no longer needed anthropologists to do it), the science of cultural variation seemed to have lost its *raison d'être*. Following the lead of Edward Said's *Orientalism* (1978), an influential critique of Western depictions of the 'East,' and often inspired by Michel Foucault, they saw anthropology as a colonial and imperialist enterprise refusing non-Western peoples a voice of their own and magnifying the distance between 'us' and 'them.' Especially in the late 1980s and early 1990s, this view had many followers, some of whom abandoned empirical research, while others tried to incorporate the autocriticism into their work. Yet others saw these pessimistic views as largely irrelevant, since anthropology had always been fraught with similar tensions, to which each new generation found its solutions. In this regard, it must be pointed out that the earlier feminist critique of anthropology, far from repudiating the subject, led to its enriching by adding new implements to its toolbox and new dimensions to its worldview. The same could be said of the reconceptualizations of culture that arguably offered an improved accuracy of description (*see* Postcoloniality).

The Situation at the Turn of the Millennium

Over the course of the twentieth century, anthropology became a varied discipline with a strong academic foothold in all continents, although its centers remained in the English- and French-speaking countries. It was still possible to discern differences between American cultural anthropology, British social anthropology, and French *ethnologie*, but the discipline was more unified than ever before – not in its views, but in its approaches. Hardly a part of the world had not now been studied intensively by scholars engaging in ethnographic fieldwork, but since the world changes, new research is always called for.

Specializations proliferated, ranging from studies of ethnomedicine and the body to urban consumer culture, advertising, and cyberspace. Although the grand theories of the nineteenth and twentieth centuries – from unilinear evolutionism to structuralism – had been abandoned, new theories claiming to provide a unified view of humanity were being proposed; for example, new advances in evolutionary psychology and cognitive science offered ambitious general accounts of social life and the human mind, respectively. The problems confronting earlier generations of anthropologists, regarding, for example, the nature of social organization, of knowledge, of kinship, and of myth and ritual, remained central to the discipline although they were explored in new empirical settings by scholars who were more specialized than their predecessors.

Anthropology has thrived on the tension between the particular and the universal; between the intensive study of local life and the quest for general accounts of the human condition. Is it chiefly a generalizing science or a discipline devoted to the elucidation of the unique? The general answer is that anthropologists ultimately do study society, culture, and humanity, but that in order to do so, they must devote most of their energies to the study of societies, cultures, and humans. As long as their mutual differences and similarities are not fully understood, there will be an intellectual space in the world for anthropology or, at least, a discipline like it (*see* Anthropology).

Anthropology: Overview

Abstract

Anthropology is a study of human diversity. This overview article discusses global variations in the delimitation of the discipline, and its development from a study closely linked historically to the Western expansion into other parts of the world, to the current situation with anthropologists from varied nations studying social and cultural life everywhere. Key concepts – culture, cultural translation, comparison, and fieldwork – are identified; main dimensions of specializations and practical applications are discussed; and the future of anthropology in an increasingly interconnected world is considered.

Anthropology as a discipline is concerned with human diversity. In its most inclusive conception, this is what brings together the four fields of sociocultural anthropology, archaeology, biological (or physical) anthropology, and linguistics. With its formative period in the historical era, when Europeans and people of European descent were exploring other parts of the world and establishing their dominance over them, and when evolutionary thought was strong, it also came to focus its attention especially on what was, from the Western point of view, distant in time or space – early humans or hominoids, and non-European peoples. In that early period, there was indeed a strong tendency to conflate distances in time with those in space: some living non-Europeans could be taken to be 'contemporary ancestors,' dwelling in 'primitive societies.' Understandings of the discipline have changed over time, however; and they are not now entirely unitary across the world. What is held together under one academic umbrella in one place may be divided among half a dozen disciplines somewhere else. A mapping of the contemporary state of the discipline, consequently, may usefully begin by taking some note of international variations.

Terminologies and Boundaries

It is particularly in North America that academic anthropology has retained what has come to be known as 'the four-field approach.' Generally, it seems to have had its greatest strength in countries where dominant settler populations faced sizable indigenous populations, and may have found it practical to assemble academic knowledge about these in a single discipline. In recent times, the continued viability of this arrangement has come under debate. Among the founders of the discipline, some were perhaps able to work (or at least dabble) in all the main branches, but with time, in American anthropology as well, it has certainly been recognized that most scholars reach specialist skills in only one of them – even as it may be acknowledged that a broad intellectual sweep across humanity has its uses, and at the same time as it is recognized that, here as elsewhere, research in the border zones between established disciplines or subdisciplines often brings its own rewards. On the whole, in any case, scholars in archaeology, biological anthropology, linguistics, and sociocultural anthropology now mostly work quite autonomously of one another, and while terminologies vary, in many parts of the world, they are understood as separate disciplines.

In Europe, varying uses of the terms 'anthropology,' 'ethnology,' and 'ethnography,' between countries and regions as well as over time, often reflect significant historical and current intellectual divides (Vermeulen and Alvarez Roldán, 1995). In parts of the continent, in an earlier period, the term 'anthropology' (in whatever shape it appeared in different languages) tended to be used mostly for physical anthropology, but since the later decades of the twentieth century, it has largely been taken over by what we here term 'sociocultural anthropology' – itself a hybrid designation for what is usually referred to either as social anthropology or as cultural anthropology (in German usage especially, however, 'anthropology' also frequently refers to a branch of philosophy). Physical or biological anthropology, meanwhile, was absorbed in many places by other disciplines concerned with human biology, while archaeology and linguistics maintained their positions as separate disciplines.

In some European countries, now or in the past, the term 'ethnography' has been used, unlike in present-day usage in Anglophone countries, to refer to sociocultural anthropology as a discipline. Matters of discipline boundaries are further complicated, however, by the fact that sociocultural anthropology, especially in Northern, Central, and Eastern Europe, is often itself divided into two separate disciplines, with separate origins in the nineteenth and early twentieth centuries. One, which was often originally designated something like 'folk life studies,' had its historical links with cultural nationalism, and concerned itself with local and national traditions, especially with regard to folklore and material culture. This discipline mostly did not acquire a strong academic foothold in those Western European countries that were most involved in exploration and colonialism outside Europe, particularly Great Britain and France, where, on the other hand, sociocultural anthropology that focused on non-European forms of life was earliest and most securely established. The more Europe-oriented, or nationally inclined, 'folk life studies' discipline has tended, in recent decades, to redesignate itself as 'European ethnology' – or, in some contexts, simply as 'ethnology' – in contrast to a rather more globally oriented 'anthropology.' In another usage, 'ethnology' has been taken to refer to a more historical and museological orientation (in contrast with what was for a time a more presentist social anthropology), while in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12011-2

other contexts again, it is more or less synonymous with 'sociocultural anthropology.' Yet further national variations in terminology continue to make direct transpositions of terms between languages treacherous.

Furthermore, if in its historical beginnings anthropology tended to be a matter of 'the West studying the rest,' with the colonial powers and their settler offshoots taking the greatest interest in establishing the discipline as an academic field, this is no longer the situation. Since the latter half of the twentieth century, the number of practitioners has grown conspicuously, and their global distribution has changed. There are now anthropologists everywhere, locals of just about all countries, based in their home academic institutions or other organizations (Fahim, 1982; Ribeiro and Escobar, 2006; Boskovic, 2008).

Yet this is not always clearly reflected in the terminology of the academic landscape. In India, where anthropology has an extended history, its distinctiveness is frequently taken to involve a particular preoccupation with 'tribal' populations, and perhaps with physical anthropology – while some of the scholars recognized internationally as leading Indian anthropologists, concerned with the mainstream of Indian society, may be seen as sociologists in their own country (Uberoi et al., 2007). In African universities, too, founded in the late colonial or the postcolonial period, there has often been no distinction made, at least organizationally, between anthropology and sociology. If in Africa, anthropology has also for a period had to carry the stigma of being historically associated with the evils of colonialism, it seems now to find its own intellectual base in a collaboration between local and expatriate scholars (Devisch and Nyamnjoh, 2011).

Back in North America and Europe, again, the framework of academic life is not altogether stable over time. 'Cultural studies,' born in Britain but expanding from there, and putting itself on the intellectual map mostly from the 1970s onward, has been most successful as a cross-disciplinary movement in the Anglophone countries but has had an impact elsewhere as well. Its center of gravity may have been mostly in literary and media studies, but insofar as it has engaged with methods of qualitative field research and with issues of cultural diversity, not least in the areas of multiculturalism and diaspora studies, it has sometimes come close to sociocultural anthropology and – in certain European countries – to ethnology, as discussed in this article. While some anthropologists may see this as an undesirable intrusion into their disciplinary domain, others see it as a source of new stimuli (Dominguez, 1996; Nugent and Shore, 1997).

Conceptions of the Core

Again, a concern with human diversity may be seen to define anthropology as a whole (Hannerz, 2010). Even when the discipline at times turns to questions of what unites humanity, and what can be seen to constitute human nature, it does so more than other disciplines against the background of its panoramic understanding of diversity. If that concern may seem somewhat airy, one can also discern its more concrete implications for many of the distinctive working realities of the anthropological practitioner. Yet there has been a somewhat shifting cluster of assumptions here of what is the core of anthropological work and thought. As we inspect it, we will concentrate on sociocultural anthropology – by now the segment of the wider field that remains, internationally, most clearly identified as anthropology.

Obviously in North America and much of Europe, the tradition of studying more exotic forms of life has remained strong, and some might still maintain that this is what a 'real anthropologist' does. Yet few are now likely to find it entirely defensible at intellectual, moral, and political levels to have a separate discipline for the study of the 'non-West' (or 'non-North'). By the latter half of the twentieth century, past vocabulary such as 'primitive societies' had certainly become mostly an embarrassment. In a more egalitarian mood, many anthropologists would now undoubtedly prefer to see the practice of research among distant others in terms of a worldwide intellectual exchange effort: it is quite acceptable for North American and European anthropologists to go to Africa, Asia, or Oceania, as long as anthropologists from these regions are also welcomed to do research in the Occident. In practice, however, such a symmetrical exchange has hardly occurred on any significant scale. The professional anthropologists originating in non-Western, non-Northern parts of the world have seldom had the inclination, or the funding, to do their research abroad. They have been much more likely to conduct their studies in their home countries – where they may thus sometimes share their fields with expatriate anthropologists from Europe or North America.

In the latter part of the twentieth century, moreover, the emphasis on studying exotic others was weakening in American and European sociocultural anthropologies as well. The growing interest in and increasing legitimacy of 'anthropology at home' have been based partly on a sense that humanity is indivisible. The preoccupation with exploring human diversity is to a certain extent retained by emphasizing the internal diversity of forms of life (lifestyles, subcultures, etc.) of contemporary societies. The exotic may be just around the corner. Moreover, the study of one's own society is often motivated by a sense of relevance: one may be better placed to engage actively with whatever are perceived to be the wrongs of the place where one has the rights and the duties of a citizen. In some parts of Europe, too, where the discipline was relatively late in getting established, most anthropologists from the very beginning did their research in their own countries, even as they drew intellectual inspiration from the classic studies of exotics imported from older national anthropologies. Of course, such a repatriation of sociocultural anthropology may again blur certain disciplinary boundaries, perhaps with sociology or perhaps in some contexts with an 'ethnology' of the European type, which could also identify itself as an 'anthropology at home.'

If anthropology is no longer quite so committed to identifying itself in terms of exotic fields, its methodology appears, in some views, to offer another sense of distinctiveness. Anthropologists, since at least the early twentieth century, have typically done 'fieldwork.' They emphasize 'participant observation' or 'qualitative research' – in contrast with the handling of more or less impersonal statistical data – or 'ethnography,' in the double sense of the process of field study and the product of a largely descriptive account of a slice or

a way of life. In this discipline, the pure theorist is an anomaly, if not entirely nonexistent. The direct involvement with another way of being and behaving, whether it is in a village on the other side of the world, in a neighborhood across town, or in another occupation, tends to become more than a methodological choice, an effective way of reaching out to something unknown. It becomes a central personal experience, a surrender with strong moral and aesthetic overtones, and a potential for rich satisfaction and lifelong memories.

Even so, placing fieldwork at the core of the distinctiveness of anthropology is also problematic. In part, the problem is that 'doing ethnography' has become increasingly common in various other disciplines as well, even if anthropologists sometimes complain that it is then done badly or superficially ('ethnography lite'). It is also true that fieldwork of the most orthodox variety does not fit readily into every setting. In all field studies, anthropologists tend to do not only participant observation but other kinds of work as well. They talk to informants, elicit life histories, collect texts, conduct surveys, and engage in some variety of activities to acquire new knowledge. To what extent their observational work can really be actively participatory must depend a great deal on the contexts. But furthermore, in contemporary life, observational work is sometimes not very rewarding. Following the daily round of an agricultural village is one thing; observing an office worker at his desk, staring at his computer screen, is another. On the other hand, fields in the present-day world may involve other kinds of data than those of classic anthropology – more media use, for example. Notions of 'field' and 'fieldwork' are increasingly coming to be debated in anthropology, as the world changes and as anthropologists try to fit their pursuits into it; there are clearly also anthropologists who prefer less distinctively anthropological methodological repertoires (cf Gupta and Ferguson, 1997; Bernard, 1998; Coleman and Collins, 2006).

The idea of gaining knowledge and understanding from fieldwork is certainly not entirely separate from the issues of where, and among whom, anthropologists work either. While anthropologists have been inclined to assume, or argue explicitly, that there are special insights to be gained from combining an outsider view with immersion in another way of life, the rise of 'anthropology at home,' the increasingly frequent copresence of indigenous and expatriate anthropologists in many fields, and the growth elsewhere in academic life of more emphatically insider-oriented fields of study, such as some varieties of ethnic studies, leave assumptions and arguments of this kind more clearly open to debate. Some would question as a matter of principle what kind of validity an outsider's perspective can have. Others could argue that one can never be an anthropologist and an insider at the same time, as these are distinct intellectual stances. And then, surely, such issues are further complicated by the fact that 'insider' and 'outsider' are not necessarily either-or categories, and hardly altogether stable either. An outsider can perhaps become an insider – and, on the other hand, one can probably start as an insider, drift away, and become an outsider. Here is an enduring complex of problems that anthropologists and their colleagues in adjacent disciplines will continue to debate (Merton, 1972; Narayan, 1993).

One may wish to object to the somewhat unreflective inclination to put fieldwork at the center of the discipline that it would tend to make anthropology primarily a methodological specialty – perhaps, because of its qualitative emphasis, the counterpart of statistics. Undoubtedly, many anthropologists would prefer to identify their discipline with particular ideas, theories, and intellectual perspectives, and the history of anthropology is most often written in such terms. It may still turn out to be difficult to point to any single, uncontested, enduring central concept, or structure of concepts.

A key idea in the exploration of human diversity has obviously been that of 'culture,' not least in the plural form of 'cultures.' This is a key term put to many uses in contemporary life (Breidenbach and Nyíri, 2009). Most fundamentally, in its conventional but multifaceted anthropological form, 'culture' stands for whatever human beings learn in social life, as contrasted with whatever is inborn (i.e., genetically given). But with the idea that human beings are learning animals also goes the understanding that they can learn different things, so that what is cultural tends to exhibit variation within humanity. Moreover, the tendency has been to conceptualize culture at a level of human collectivities (societies, nations, and groups), so that members are held to be alike, sharing a culture, while on the other hand there are cultural differences between such collectivities. Culture, that is, has been taken to come in distinct packages – cultures. In the classic view of culture, there has also been a tendency to try to see each such culture 'as a whole' – to describe entire ways of life and thought, and to throw light on the varied interconnections among ideas and practices.

Such a basic notion of culture has allowed anthropologists to proceed with the task of drawing a panoramic map of human diversity. There has certainly also been a widespread preoccupation with showing how much of human thought and behavior is actually cultural (i.e., learned) and thus variable, rather than altogether biologically based and uniform. This emphasis has been visible, for example, in anthropological contributions to gender studies.

Yet culture has also been a contested concept in anthropology, not least in recent times. It is true that it was never equally central to anthropological thought in all varieties of anthropology. American sociocultural anthropology, which has more often been identified as 'cultural anthropology,' has focused rather more on it, for example, than its British counterpart, which has been more inclined over the years to describe itself as 'social anthropology.' By the late twentieth century, however, critics in the United States as well as elsewhere argued that the established style of cultural thought tended to exaggerate differences between human collectivities, to underplay variations within them, to disregard issues of power and inequality and their material bases, and to offer overly static, ahistorical portrayals of human ways of life. While some anthropologists have gone as far as to argue for the abolition of the culture concept, others would be inclined to accept many of the criticisms yet take a more reformist line. Whichever view is taken, it seems that debates over the understanding of culture offer the discipline one of its lively intellectual foci (Hannerz, 1993; Brumann, 1999; Kuper, 1999).

The notion of cultural translation has also had a part in defining anthropological work, and inevitably it is drawn into the arguments about the culture concept generally. Indeed, bridging cultural divides by making the ideas and expressions

of one culture understandable in terms of another has been a major anthropological activity, although this linguistic analogy is certainly too limiting to describe all anthropology (Asad, 1986; Pálsson, 1993). In a somewhat related manner, it has gone with the interest in human diversity to describe anthropology as a discipline centrally involved with comparison (Gingrich and Fox, 2002). In a general way, this is clearly valid. Much of anthropology is at least implicitly comparative, in its inclination to emphasize what is somehow notably different about the ideas, habits, and relationships of some particular population. To the extent that the origins of the discipline have been European and North American, the baseline of such comparisons and contrasts has no doubt been in a general way Western. At the same time, there has been a strong tendency to use the knowledge of diversity to scrutinize Western social arrangements and habits of thought, and thus to destabilize 'common sense.' In such a way, anthropological comparison can serve the purpose of cultural critique, a possibility used in different ways at different times (Marcus and Fischer, 1986). On the other hand, the form of large-scale comparative studies, focusing on correlations between particular sociocultural elements across a large number of social units, which was prominent in the discipline in some earlier periods, has not been a central feature for some time, and the intellectual and methodological assumptions underlying comparison are also a more or less continuous topic of argument (Köbben, 1970; Holy, 1987).

Specialties and Subdisciplines

If culture in the singular and plural forms, fieldwork, translation, and comparison may count as ideas and practices that hold anthropology together, not in consensus but often rather more through engagement in debate, it is often suggested that the discipline also tends to be systematically segmented along various lines – not only in terms of what is understood to make up the discipline, as noted in this article, but also with regard to what draws communities of specialists closer together. One of the three major dimensions here is area knowledge. Anthropologists tend to be Africanists, Europeanists, Melanesianists, or members of other region-based categories. Rather few of them ever commit themselves to acquiring specialized knowledge of more than one major region to the extent of doing field research there. It is true that if fieldwork is often highly localized, it does not necessarily lead to a wider regional knowledge either, but as a matter of convention (perhaps at least to fit into normal job descriptions in the discipline), the tendency has been to achieve specialist status by reaching toward an overview of the accumulated anthropological knowledge of some such unit, and perhaps seeking opportunities to familiarize oneself with more of it through travel. In countries where 'area studies' have been academically institutionalized, such regional anthropologies have had a significant role in the resulting interdisciplinary structures, and, generally, shared regional specialization has often been important in scholarly exchanges across discipline boundaries.

The second major dimension of specialization can be described as topical. Although anthropology has a traditional orientation toward social and cultural 'wholes,' there is yet a tendency among many anthropologists to focus their interest on particular kinds of ideas, practices, or institutions. Frequently, such specializations have tended to follow the dominant dividing lines between other academic disciplines – there has been political anthropology, economic anthropology, psychological anthropology, anthropology of law, anthropology of art, and ecological anthropology, for example. Drawing on knowledge of social and cultural diversity, one aspect of such specialization has been to scrutinize and criticize concepts and assumptions of the counterpart disciplines with respect to their tendencies toward Western-based intellectual ethnocentrism; but obviously there is also a continuous absorption of ideas from these other disciplines. Here, then, are other interdisciplinary connections. It may be added that such subdisciplines often have their own histories of growth in some periods, and stagnation in others (Collier, 1997).

Thirdly, anthropologists sometimes specialize in the study of broad societal types, based on dominant means of livelihood – hunter-gatherers, peasants, pastoralists, fishermen, and so forth. In some ways, urban anthropology may be seen as a similar kind of specialty. In fields like these, too, intensities of collective engagement and intellectual progress have tended to vary in time.

The Practical Uses of Anthropology

It has occasionally been argued that anthropology is less engaged with practical application than many other academic disciplines, and more concerned with achieving a somewhat lofty overview of the human condition, in all its variations. One factor underlying such a tendency may be a sort of basic cultural relativism – it may go with the acceptance, and even celebration, of human diversity to be somewhat skeptical of any attempt to impose particular arrangements of life on other people. This stance may well be supported by the fact that anthropologists have often been outsiders, working in other societies or groups than their own, and feeling that they have no mandate for meddling, or for that matter any actual realistic opportunity.

Nonetheless, there have always been a number of varieties of 'applied anthropology.' In an early period, when the study of non-Western societies was carried out in contexts of Western colonialism, it was held that anthropological knowledge could be useful in colonial administration. While some administrators had anthropological coursework before taking up their overseas assignments, and while some anthropologists did research oriented toward such goals, it seems that such connections remained rather limited, and administrators were often impatient with the anthropologists' preference for a long-term buildup of basic knowledge. Particularly toward the end of the colonial period, anthropologists also often saw such involvements as morally and politically questionable.

In the postcolonial era, anthropological knowledge became engaged in a larger scale, and in many different ways, in development work in what had now (at least for some time) turned into the 'Third World.' Many governments, international agencies, and international nongovernmental organizations have thus drawn on anthropological advice, and have

offered arenas for professional anthropological activity outside academia. At the same time, with 'development' turning into a global key concept, around which an enormous range of activities and organizations revolve, this again has become another focus for critical theoretical scrutiny among anthropologists (Dahl and Rabo, 1992; Escobar, 1995). In recent times, particularly in the United States, there has also been considerable debate over the uses of anthropological expertise in contexts of war and other international conflict (Kelly et al., 2010).

When anthropologists work in their own countries, the range of applications may be wider, and as already noted, practical and political relevance is frequently one reason for doing anthropology 'at home.' Not least as transnational migration has made more societies increasingly ethnically and culturally heterogeneous, anthropologists have been among the social scientists engaged, in one way or other, in the handling of minority affairs and multiculturalism. Educational and medical anthropology are not always involved in practical application, and research in such fields is also carried out in societies other than the researcher's own, but often work in these subdisciplines similarly centers on the encounter between major institutional complexes and culturally heterogeneous populations. Some number of anthropologists in Europe and North America now also make use of their disciplinary perspectives as specialists on organizational culture, and as marketing analysts, in a growing field of business anthropology (Moeran, 2005). A further practical field that emerged in the late twentieth century as its own profession is 'intercultural communication,' which offers training and consultancy in the handling of concrete situations of cultural difference and, putting it somewhat dramatically, 'culture shock.' This field has links to several academic disciplines, but to a considerable degree it draws on a more or less anthropological conception of culture – of a type, it may be added, that many anthropologists might now find rather old-fashioned and clumsy.

The Future of Anthropology

In all its varying shapes, in space and over time, anthropology has tended to straddle conventional academic classifications of disciplines. In its scope of subject matter – for example, family and kinship, politics, and market and exchange, on the one side, and art, music, and dance, on the other – it extends across the social sciences and the humanities. Insofar as it has to take into account the biological givens of human thought and action, and inquires into the interactions of humankind with its natural environment, it reaches into the natural sciences as well. But its multiple affiliations are not only a consequence of its varied subject matter. They are also implied in the variety of intellectual approaches: in field research, in theoretical work, and in styles of presentation. In what ways, or to what extent, anthropology is an art or a science continues to be a matter of lively internal debate.

In many ways the enduring characteristics of anthropology, throughout this range of forms, continue to be expressions of the concern with diversity – with the highly varied manners of being human. To the global public stock of ideas, it brings such notions as taboo, witchcraft, cargo cults, totemism, or the potlatch exchange feasts of Northwest Coast American Indians. Concepts such as 'Big man' (out of Melanesia), 'patron–client relationships' (not least out of the Mediterranean area), or 'caste' (out of India), allowed to travel out of their areas of origin, can enrich our thinking about power, politics, and inequality in many contexts. There is a rich intellectual universe here, to be drawn on within the discipline and from outside it. And anthropology has its classic preoccupations, such as ritual or kinship, concerning which new materials about yet more variations are continuously gathered worldwide, and around which theoretical debates never seem to cease.

At the same time, anthropology goes on reconfiguring itself (cf Wolf, 1964; Hymes, 1972; Fox, 1991; Ingold, 1996; Rabinow et al., 2008). One might perhaps have thought that a discipline revolving around the diversity of human forms of life and thought would find itself in difficulty at a time when increasing global interconnectedness may lead to cultural homogenization, and a loss of local or regional cultural forms. Indeed, it is true that many people in the world no longer stick to the beliefs they used to hold, and are discarding some of their past practices, ranging from spirit possession to headhunting. In part, the responsibility of anthropology here becomes one of preserving a record of the ways of humans, past and present, and keeping that record alive by continuing to scrutinize it, interpret it, and bring it to bear on new developments.

It is also true, however, that diversity is not diminishing as much as some, perhaps fairly superficial, views of globalization might suggest. Traditions may be remarkably resilient, adapting to new influences and absorbing them in various ways; there may be more than one 'modernity.' Moreover, new interconnections may generate their own social and cultural forms, so that there may be cultural gain as well as cultural loss. A growing interest in anthropology with such notions as hybridity and creolization bears witness to this. In addition, however, anthropology has continuously expanded the field of social and cultural variations with which it has actively engaged. As the discipline was practiced in the earlier decades of the twentieth century, one might have discerned a tension between, on the one hand, the ambitious claims of offering a view of humanity, and, on the other hand, the actual concentration on villages of horticulturalists, bands of hunter-gatherers, or other exotic and small-scale sociocultural arrangements. But then by the mid-twentieth century, there was an increasing involvement with peasant societies, and the civilizations of which they were a part, and later yet urban anthropology appeared as another subdiscipline, practiced in field settings in every region. In recent times, the anthropology of science has been another growing specialization, as the practices of scientists are scrutinized as yet another kind of cultural constructs, and as laboratories are added to the range of possible sites of fieldwork (Rabinow, 1996; Downey and Dumit, 1997). It appears, consequently, that the enduring wider claims of the discipline to an overall engagement with human modes of thought and action are increasingly being realized.

Obviously, in many of its fields of interest, anthropologists now mingle with scholars from a variety of other backgrounds, and the division of labor between disciplines here may not seem obvious. Undoubtedly, there are blurred boundaries as well as cross-fertilization, but anthropologists would emphasize

the intellectual potential of a conceptual apparatus trained on, and informed by a knowledge of, a great variety of cultural assumptions and institutional arrangements. There is also the commitment to close-up observation of the relationships between human words and deeds, and the strain toward understanding 'wholes,' which, despite its vagueness, may usefully involve a particular commitment to contextualization as well as skills of synthesis.

Anthropologists now find themselves at work in a global ecumene of increasing, and increasingly polymorphous, interconnectedness. This is a time in which that diversity of social and cultural forms with which they are preoccupied is constantly as well as rapidly changing, and where new social, political, economic, and legal frameworks encompassing and rearranging that diversity are emerging. More people may have access to a larger part of the combined human cultural inventory than ever before; conversely, whether one likes it or not, more of that cultural diversity can also come in one's way. This is also a time when debates over the limits of diversity are coming to new prominence, for different reasons. Evolutionary biologists are setting forth new views of human nature that need to be carefully confronted with understandings of cultural variation. As people sense that they live together in one world, questions also arise over what is, or should be, shared humanity, for example, in the area of human rights (Wilson, 1997; Goodale and Merry, 2007). There would seem to be a place in the public life of this era for a cosmopolitan imagination that both recognizes diversity and seeks the ground rules of a viable and humane world society. For such a cosmopolitan imagination, one would hope, anthropology could continue to offer materials and tools.

Abstract

Antidepressants are psychotropic drugs for the treatment of depressive syndromes of various etiologies. This historical definition nowadays reflects only one facet of the spectrum of their possible therapeutic applications. More than 40 years of clinical experience and scientific research with antidepressant drugs have resulted in a variety of different indications with proven efficacy for these agents, particularly anxiety disorders or obsessive–compulsive disorder. As antidepressants are effective across different psychopathological syndromes of traditional nosological categories, an up-to-date definition for this heterogeneous group of agents with different chemical structures and pharmacological profiles still needs to be established.

Because of historical developments, a stringent classification for all available agents with antidepressant properties has not yet been agreed upon. Initial classificatory attempts focused on the chemical structure of the drugs. Recent classifications emphasize the pharmacological profile of the drug. This latter approach is of greater clinical relevance, because it depicts the primary target sites in the central nervous system (e.g., transporter proteins or various receptor subtypes), allowing a better prediction of the potential clinical application and the side-effect profile of the drug. As a result of both approaches, many clinicians today distinguish the following groups of antidepressants: (1) monoaminooxidase inhibitors (MAOI), (2) tricyclic antidepressants (TCA), (3) selective serotonin reuptake inhibitors (SSRIs), and (4) antidepressants with different pharmacological profiles. In addition, drugs initially developed for other indications have shown some promising effects as antidepressants, such as anti-inflammatory medications.

History

Monoaminooxidase Inhibitors

Iproniazid and its precursor isoniazid had been developed in the laboratories of the company Hoffmann-La Roche primarily as antituberculosis agents. As a consequence of casuistic observations on mood-elevating properties of iproniazid, this effect was first confirmed by Loomer et al. (1957) in a clinical trial. However, significant hepatotoxicity was observed during iproniazid treatment. Subsequent development of drugs inhibiting monoamine oxidase (MAO) systems led to the introduction of isocarboxazid, phenelzine, and tranylcypromine as irreversible inhibitors of MAO. Their use has been limited because of possible hypertensive crises after ingestion of food containing large amounts of tyramine, forcing patients to follow dietary restrictions during pharmacotherapy with these drugs. This led to the development of reversible monoaminooxidase inhibitors (MAOI) such as moclobemide, which no longer required dietary restrictions.

Tricyclic Antidepressants

After the discovery of the antipsychotic effects of chlorpromazine in 1952, the compound G22355, later called imipramine, was developed in the laboratories of the company Geigy. Imipramine was a derivative of chlorpromazine and was first tested in clinical trials in schizophrenia. While no relevant antipsychotic effects were noted, mood-elevating effects in patients with a co-occurring depressive syndrome were observed. At this point, both the company and the clinical investigator Kuhn decided to test imipramine in patients with depression as a potential antidepressant. The results of the clinical trials were first published in 1957, and are still a remarkable document of skillful clinical observation, as the report contains many details about the antidepressant effects of imipramine which still hold true today (Kuhn, 1957).

A variety of compounds that were chemically related to imipramine have been developed. They all shared the basic chemical structure of a tricyclus. Subsequent research revealed that in most instances, while the tricyclic basal structure was preserved, minor alterations of its side chains resulted in markedly different pharmacological profiles of the drugs. The chemically related compound maprotiline, often termed a tetracyclic, was developed as a consequence of systematic variation of the tricyclic structure.

From the 1960s to the 1980s, the tricyclic antidepressants (TCA) were the dominating group of antidepressants in clinical practice throughout the world. As many of the TCA compounds induce substantial side effects, they gradually lost their predominance with the availability of the selective serotonin reuptake inhibitors (SSRIs) during the 1990s.

Selective Serotonin Reuptake Inhibitors

In the 1970s, on the basis of increasing knowledge about the mechanism of action of MAOI and TCA, pathophysiological models of depression were proposed. Consequently, potential antidepressants with more specific neurotransmitter receptor effects were developed. According to the norepinephrine depletion hypothesis of depression, drugs to selectively potentiate central noradrenergic neurotransmission were developed. On the other hand, the various available TCAs were scrutinized for their potency of serotonin reuptake inhibition. Clomipramine was shown to have the strongest effects on serotonin reuptake inhibition; however, the substance does not only selectively inhibit the serotonin transporter but also shows effects on norepinephrine.

Subsequently, in a collaboration between a pharmaceutical company (Astra) and the research team of Carlson in Sweden, the first SSRI zimelidine was developed. The first results from a clinical trial on zimelidine were published in 1977 (Benkert et al., 1977). However, the antidepressant had to be withdrawn from the market because of the emergence of neurological side effects.

In the 1980s, fluoxetine ('Prozac'), an SSRI developed by Eli-Lilly Company, was made available in the USA. The introduction of this drug represents the breakthrough of SSRIs in the treatment of depression. Successful marketing strategies and the low toxicity of fluoxetine may explain the broad spectrum of indications for this drug. The prescription of fluoxetine in patients with personality disorders and, finally, the use of Prozac by healthy people to improve their general wellbeing, led to an ongoing discussion regarding the acceptability of so-called 'lifestyle' drugs.

In the following years, four additional SSRIs were approved: fluvoxamine, paroxetine, sertraline, and citalopram. The latter two substances have favorable pharmacokinetics and a low risk for drug–drug interactions – an issue that became increasingly important in the 1990s.

Antidepressants with Different Pharmacological Profiles

The introduction of selective antidepressants reduced the rate of unwanted side effects. The higher selectivity of these drugs was, however, not accompanied by higher efficacy. Therefore, research and drug development focused on compounds which exerted their effects on different and interrelated neurotransmitter receptors in the brain to enhance their benefit–risk ratio based on theoretical reasoning about the anticipated profile of effects and side effects.

The push to develop highly selective antidepressants targeting a single type of neurotransmitter receptor or transporter had ended. Highly effective and well-tolerated drugs like mirtazapine, venlafaxine, and, more recently, agomelatine, are examples of the new strategy of drug design.

Rather independent from this line of progress, the herb St. John's Wort has achieved great popularity throughout the world, based on the drug's low toxicity, its high acceptance, and a proven efficacy in the treatment of mild to moderate depression. The exact mechanism of action is not completely known.

Mechanism of Action of Antidepressants

There is considerable evidence that many antidepressants facilitate neurotransmission of one or more monoamines – serotonin, norepinephrine, or dopamine. This effect appears to be mediated by different mechanisms that are described in the following sections.

Blockade of One or More Types of Synaptic Monoamine Transporters

Synaptic monoamine transporters are protein structures which rapidly retrieve released neurotransmitter molecules from the synaptic cleft into the originating neuron. By specifically blocking the transporter, the reuptake of the neurotransmitter is hampered, thus increasing its availability in the synapse. Examples of compounds that predominantly or selectively inhibit the reuptake of serotonin are the SSRIs listed above, or the tricyclic compound clomipramine. Drugs predominantly or selectively inhibiting the norepinephrine reuptake are reboxetine, and the tricyclic compounds desipramine and nortriptyline. Many antidepressants block both the serotonin and norepinephrine transporter, more or less with the same potency, for example, imipramine, amitriptyline, doxepine, milnacipran, or venlafaxine. Examples of dopamine reuptake inhibitors are bupropion (also affecting norepinephrine uptake) or amineptine.

Blockade of the Enzymes That Inactivate Monoamines

The main enzyme relevant in this context is the MAO. Its isoform MAO-A degrades mainly serotonin and norepinephrine, while MAO-B predominantly metabolizes dopamine. MAO can be blocked irreversibly and unselectively by compounds such as phenelzine or tranylcypromine. Reversible MAO-A inhibitors such as moclobemide selectively block the metabolism of serotonin and norepinephrine within therapeutic ranges. Selective MAO-B inhibitors have not consistently proved to be antidepressants.

Stimulation and/or Blockade of Receptor Subtypes

In this category, various compounds with different modes of action are mentioned. From the tricyclic compounds, trimipramine blocks dopamine D2, alpha-1-adrenergic H1-histaminergic, and muscarinic receptors without any substantial effect on monoamine transporters. Mirtazapine blocks alpha-1 and 2-adrenergic receptors, as well as 5-HT_2 and 5-HT_3 and H1 histaminergic receptors. Nefazodone mainly blocks 5-HT_2 receptors, with weak inhibition of serotonin and norepinephrine uptake. The most recent development in novel pharmacological strategies is agomelatine, a drug that has antagonist activity at serotonergic (5HT2C) receptors and agonist activity at melatonergic (MT1/MT2) receptors.

The pharmacological profile of most antidepressants has been well characterized, providing an explanation for some of the acute and prolonged effects of these agents. In particular, the side-effect profile of antidepressants can be readily derived from their pharmacological profile. However, the postulated enhancement of monoaminergic function may not be the only or even the crucial factor explaining why antidepressants work. The pharmacological profile of a drug does not sufficiently explain its antidepressant properties. This is borne out by the following findings:

1. The pharmacological target sites within the CNS are affected within minutes after administration of the drug. Many side effects of these agents occur early in the course of treatment, in good time correlation with the administration of the drug. However, virtually all antidepressants need several days to weeks of regular application until their full therapeutic effect becomes clinically visible.
2. Other pharmacological agents acting as monoamine reuptake inhibitors comparable to the above-mentioned

antidepressant drugs have not been found to possess convincing antidepressant properties (e.g., cocaine, amphetamine).

Several hypotheses have been developed to explain the delay of full antidepressant effects. It has been postulated that the effects of antidepressants at their primary target sites (receptors or transporters as first messengers) induce secondary effects, for example, adaptatory changes in intracellular signal transduction at the level of second messengers (such as the adenylyl cyclase system) or of gene expression. This may lead to altered receptor sensitivity (as described for beta-adrenergic receptor down-regulation or decreased sensitivity of serotonergic receptors, such as 5-HT_2 receptors). Changes of the synthesis of brain-derived neurotrophic factor and/or alterations of the hypothalamic–pituitary axis may represent pathways by which antidepressants finally exert their therapeutic effects. Changes in synthesis of protein structures might explain the time lag needed for antidepressants to develop their full therapeutic effect on mood and affect. More recently, clinical trials have demonstrated antidepressant effects by drugs with anti-inflammatory action, indicating that increased inflammation maybe one of the mechanisms by which depression lead to disrupted brain function (Fond et al., 2014).

Indications

By now, many drugs with antidepressant effects have also been evaluated as effective agents in several indications, which are briefly outlined below.

Depressive Disorders

The classical indication for TCA, MAOI, SSRI, and other antidepressants is depressive episodes (e.g., major depression). Their use is the treatment of choice in moderate or severe depression. Antidepressants are effective both in acute treatment and in preventing relapse of unipolar depression during long-term treatment (continuation or maintenance phase, after the acute symptoms have been treated effectively). Several authors have found that depressive episodes with melancholic features are more likely to respond to drug treatment than to psychotherapy. So-called atypical depressive episodes are reportedly more likely to respond to MAOI (and perhaps to SSRI) than to TCA such as imipramine. In the treatment of psychotic depression, the combination of an antidepressant with an antipsychotic is warranted. Contrary to former belief, long-lasting mild to moderate depressive states, currently labeled as dysthymia, also respond well to antidepressant drug treatment in a majority of cases. In bipolar disorder, the use of antidepressants during a depressive episode may trigger a switch into a manic state; therefore their use in this indication is currently a matter of debate.

Panic Disorder

Starting with TCA such as imipramine or clomipramine, a variety of antidepressant drugs have been demonstrated to be an effective treatment in panic disorder with or without agoraphobia. Currently, SSRI are the treatment of choice in this indication, if a drug treatment with an antidepressant is established. SSRI have shown convincing anxiolytic properties in combination with a favorable side-effect profile for a majority of patients.

Obsessive–Compulsive Disorder

This often chronic and disabling disorder, characterized by intruding thoughts or repetitive compulsions that often are time-consuming and may interfere considerably with an individual's functioning, seems to respond selectively to compounds such as clomipramine or SSRI that act as predominant or selective serotonin reuptake inhibitors, because norepinephrine reuptake inhibitors or MAOIs have not consistently shown therapeutic effects in this indication.

Generalized Anxiety Disorder

In the treatment of this chronic anxiety disorder characterized by waxing and waning anxiety symptoms and excessive worrying, several antidepressants such as SSRI or venlafaxine have demonstrated beneficial effects in reducing cognitive anxiety symptoms in particular.

Social Phobia

MAOI and SSRI are effective in the treatments for this disorder, characterized by marked anxiety in social situations, where the individual is exposed to unfamiliar people or to possible scrutiny by others.

Bulimia Nervosa

This disorder, with recurrent episodes of binge eating, loss of control, overeating impulses, and inappropriate compensatory behavior to prevent weight gain, can also be beneficially influenced by antidepressants. Binge frequency and purging behavior in particular can be significantly reduced by regular treatment.

Premenstrual Syndrome

Symptoms of tension, dysphoria, and irritability, accompanied by various somatic complaints and occurring during the late luteal phase of the menstrual cycle, can be effectively treated by continuous or intermittent administration of SSRI or clomipramine. As in the case of OCD, there is evidence that only predominant or selective serotonin reuptake inhibitors are effective from the spectrum of antidepressant drugs.

Further Indications

Antidepressants have also been demonstrated to be of therapeutic value in the treatment of pain syndromes of various etiologies, in the prophylaxis of migraine, in the treatment of posttraumatic stress disorder, in the treatment of children with enuresis or attention-deficit and hyperactivity syndromes, or in patients with narcolepsy (especially clomipramine). SSRI may also be of therapeutic value in treating premature ejaculation,

obesity, or anger attacks associated with mood or personality disorders. In impulsive and affectively unstable personality disorders (e.g., borderline personality disorder) SSRI may be beneficial, whereas MAOI may be helpful in avoidant personality disorder.

Therapeutic Principles

If treatment with antidepressant drugs is established, the prescribing clinician and the treated patient need to consider some general guidelines, which apply to most indications for which these agents have been evaluated:

1. Treatment with antidepressants generally requires continuous treatment over several weeks on a regular basis; intake on an as-needed base generally is not sensible.
2. Therapeutic effects generally develop gradually during continuous treatment with antidepressants. In a majority of cases, 2–3 weeks are needed until more than 50% of symptom reduction is achieved.
3. During the course of treatment, side effects usually appear before the desired therapeutic effect reaches its maximum. This particular issue needs to be clarified with the patient in order to ensure compliance with treatment up to the point of clinical remission.
4. Antidepressants need to be given in a sufficiently high dose to achieve optimal treatment effects. Efficient doses for TCA usually lie between 100 and 300 mg day^{-1}, SSRI such as citalopram, fluoxetine, or paroxetine need 20 mg day^{-1} and sertraline or fluvoxamine, at least 50 mg day^{-1}. Depending on the side-effect profile of a drug, initial treatment requires gradual dose increase until effective doses are achieved (for TCA recommended starting doses are 25–50 mg day^{-1}; SSRI can usually be started with the minimal effective dose).

After remission is reached, it is generally recommended to maintain the effective dose for at least several weeks or months in order to prevent recurrence of the symptoms or relapse. In cases of known high risk of recurrence, continued treatment over years is needed. Combining antidepressant drug treatment with psychotherapy (especially cognitive–behavioral or interpersonal therapy) usually provides additive benefit for the patient; both approaches are not contradictory.

Recent large, naturalistic clinical studies have shown that most antidepressant strategies (including augmentation, combinations, and switching) are equally effective, and that around 25% of patients do not respond to any available antidepressants (Rush, 2011). However, other authors have compared data from large datasets of clinical trials and identified that some antidepressants, such as sertraline, escitalopram, and venlafaxine, are more effective than others (Cipriani et al., 2006).

Antidepressants do not have 'addictive' properties, but a discontinuation syndrome has now been recognized, with symptoms including symptoms such as nausea, vomiting, diarrhea, headaches, sweating, insomnia, tremors, and vertigo, as well as mood disturbances that may be mistaken as depression relapses. This has led to clear guidelines indicating the need for the slow tapering of the dose before stopping any antidepressants.

Disputable Issues: Ethical, Methodological, and Clinical

Despite the widely accepted beneficial effects of antidepressants, there is ongoing debate on how these effects and benefits can be assessed. The scientific gold standard established over a period of about 50 years, and representing the basis of approval of new antidepressant drugs by legal authorities, is to assume *efficacy* of antidepressants if they are clearly superior to placebo in at least two well-conducted randomized controlled trials. Ethical issues are primarily related to the use of placebo in such pivotal trials. A recent study has shown that suicide rates and mortality in patients treated with placebo in randomized controlled trials were not discernible from those of patients treated with an antidepressant verum (Khan et al., 2000).

The demonstration of efficacy of antidepressants in controlled clinical trials is necessary but not sufficient for evaluating the therapy of major depression and related disorders. The focus of interest is shifting from pure efficacy to *effectiveness* studies of antidepressants. This implies asking the question whether a treatment still works when used by the average clinician with the average patient in an average therapeutic setting. Additionally, *efficiency* studies are essential to assess the required level of resources to produce reasonable benefit. Research at the interface of clinical trials and effectiveness studies, including cost–utility and econometric studies, is indispensable to estimate the benefit and the shortcomings of available antidepressant drug therapy (Wells, 1999).

Evidence from double-blind, placebo-controlled trials of antidepressant drugs from all classes has shown them to be effective in alleviating symptoms in approximately 60–75% of patients with major depression. In contrast, the placebo response rate averages 35% after 1 month of treatment. However, the very high variability of verum and placebo responses makes it nearly impossible to extrapolate from one study to another or from the results of a clinical trial to real clinical situations. This variability of study outcomes can be reduced by patients' selection based on DSM-IV criteria, and by clinicians trained on standard depression assessment scales. A symptom reduction of at least 50%, for example, in the Hamilton Depression Rating Scale score, is widely used as an arbitrarily chosen but operational measure of treatment response. However, a 50% improvement may leave many patients with significant symptoms, and, paradoxically, it is more difficult to achieve a 50% response if the baseline severity of depression is high. As a consequence, antidepressant drug efficacy in less severely depressed patients is not easily demonstrable, although most of these patients require effective treatment.

The effects of antidepressive drugs are seen in all of the symptoms of major depression; however, vegetative symptoms, for example, sleep disturbances and loss of appetite, are often the most rapidly improved. When only a single global measure is used to assess depression severity or improvement, differential drug effects and differential response patterns in subgroups of patients are overlooked. Thus, the methodology used for the assessment of symptoms and symptom changes, as well as the distribution of prevailing symptoms in different patients' samples, can influence study results. There is still

a lack of studies considering these issues and other factors which can potentially influence treatment response, for example, patients' gender, age, or personality.

Furthermore, the efficacy of antidepressants is often confounded with the time course of improvement. There is still controversy over whether or not some antidepressants exert a faster onset of action. Survival–analytical approaches (Stassen et al., 1993), exponential recovery models (Priest et al., 1996), and pattern analyses (Quitkin, 1999) are statistical methods to assess differential dynamics of improvement under antidepressants. There are additional important clinical and methodological issues relevant to treatment with antidepressant drugs.

One of these issues is the question whether patients with mild or moderate depression should be pharmacologically treated. This issue is linked to the issue of reliable screening and diagnosis.

There is a lack of convincing trials on the comparative and combined effectiveness of biological and psychological treatments in depression. Despite the long experience in the use of antidepressants and psychotherapy, there is no evaluation standard for these issues.

Another controversy directly related to mental health policy is the recommendation of antidepressants to prevent manifestation of major depressive disorder at an early stage, when only prodromal or single symptoms are present. This issue also includes the questionable prescription of antidepressants for children and adolescents – a generally underinvestigated field.

Secondary prevention, that is, reducing the risk for recurrence and chronicity of depressive disorders, also raises the question of how long antidepressants should be prescribed after remission of the target symptoms. The potentially advantageous prophylactic use of antidepressants is challenged by the risk of triggering switches into manic states, particularly in bipolar disorder. Decisive studies are required to demonstrate which antidepressants have the lowest risk for mood switches and phase acceleration.

Conclusion and Future Prospects

Today, a respectable armamentarium for the treatment of depressive disorders is at hand, and antidepressants are standing in the front line. When used adequately, the available antidepressant drugs are effective in reducing an enormous burden of costs, distress, suffering, and death.

Notwithstanding the tremendous progress in the field of antidepressant drugs the ultimate goals have not yet been reached. The key objectives of antidepressive drug treatment remain as follows:

1. to reduce and ultimately to remove all signs and symptoms of the depressive syndrome in the largest possible proportion of patients in the shortest possible time;
2. to restore occupational and psychosocial function to that of the asymptomatic state; and
3. to attenuate and ultimately to eliminate the risk of relapse, recurrence, and chronicity.

There is still an urgent need to develop new and better treatments for depression, including drugs and other biological treatments, psychotherapeutic strategies, and combinations of some or all of these. The benefit of having a wide array of antidepressant drugs and other treatment options is based on evidence that there may be different forms of the illness, which respond to different mechanisms of action. More research is needed to develop predictors of differential responsiveness in order to tailor antidepressant treatment to the individual patient's requirement (Preskorn, 1994).

Depression is – among other neurological and psychiatric disorders – at present a treatable, but still little understood, disease. From the very beginning, the history of antidepressive drug treatment was accompanied by scientists' expectation that the knowledge about the mechanism of action of antidepressants would lead to an extended insight into the biological nature of the treated illnesses. In fact, the progress in research on antidepressants had an immense impact on biological psychiatry. However, there is still a lack of knowledge concerning the molecular understanding of the etiology and pathophysiology of depression, and the complex mechanisms of action of antidepressant drugs are still enigmatic.

Despite the chemical and pharmacological diversity of the presently available antidepressant drugs, they have some properties in common. The differences between antidepressant drugs lie mainly in side effects, tolerability, and the potential for pharmacokinetic interactions. Regarding the mechanism of action of the diversity of available antidepressants, a final common pathway is likely to be involved. A modulation of a number of different types of neurotransmitter receptors seems to contribute to the long-term effects of antidepressants, in most cases irrespective of the acute effects of the diversity of available drugs on a particular system. On a higher level of action, shared effects of different antidepressants on second-messenger systems and gene expression can be assumed but specific data are not available. For instance, an active cross-talk between serotonergic and noradrenergic receptors which can be modulated by a protein kinase has been demonstrated. Furthermore, a link between central glucocorticoid receptors and neurotransmitter receptor systems is likely.

Promising new candidates of alternative mechanisms of action for novel antidepressive drugs include inflammation, as mentioned above, and neurotrophic factors, especially following the recent evidence that the fast-acting antidepressant, ketamine, activates these mechanisms zunszain (Zunszain et al., 2013). It does not seem overoptimistic to expect that with the rapid progress of genetic and molecular research, the core pathophysiology of depressive disorders could be elucidated in the near future. This attainment alone could provide a rationale for a causal therapy of depression and related disorders and for logically designed antidepressant drugs with a clear therapeutic superiority over those available today.

Superiority should be in future understood not only in terms of higher efficacy, but also with regard to lower toxicity, better subjective tolerability and treatment adherence, improved functional outcome, and quality of life. The increasingly available evidence should serve as the basis for the prescription of a particular drug to a given patient. Long-term mental health issues for the development of better antidepressants should be the cost-effective reduction of patients' disability, morbidity, and mortality caused by depression and related disorders.

Abstract

This article discusses social work compliance with antisemitic policies under National Socialism and the strengths and limitations of addressing this record of compliance through ethical frameworks provided by professional bodies. It addresses factors that militate against learning from this history of compliance: textual silences about antisemitis, the radical separation of the present from the past, and the disconnection of antisemitism from other forms of racism. It confronts the difficult relation between antisemitism and the 'Israel question' and how professionals today might think about the challenges antisemitism continues to pose.

Introduction

We explore social work compliance with antisemitic policies under National Socialism and the strengths and limitations of addressing this record of compliance through ethical frameworks provided by professional bodies. We address three impediments to learning from history: textual silences about antisemitism, the divorce of the present from the past, and disconnection of antisemitism from other racisms. We address the relation between antisemitism and criticism of Israel and how professionals today might think about the challenges antisemitism poses.

Compliance: Antisemitism in Social Work under National Socialism

Sünker and Otto (1997) plot a radical shift under National Socialism from a system of welfare whose primary values were universalistic and based on the care of the individual, to one centered on education for the strengthening of the *Volk* community and the elimination of those categorized as 'useless.' Social work practice and policy accommodated this shift largely by donning a defensive professional mask rather than through enthusiastic embrace, although this mask was unavailable to Jewish social workers and other social workers who fell victim to political and antisemitic purges (Schnurr, 1997: 126; Burleigh, 1994: 170–171). The remaining social workers kept their jobs to administrate the demands of the new regime. They participated in National Socialist (NS) pedagogic projects to instil true German self-reliance instead of welfare, worked in educational camps and cultivated NS values about motherhood and community in maternity training programs.

NSs held that certain categories of the population (disabled, mentally defective, racially impure, sexual deviants, political dissenters) were 'useless' to the foundation of a new Germany, and that the ideologically and economically sound way of dealing with these groups was to confine, sterilize, or murder them. At the same time the 'useful' were to be supported to help grow a hygienic nation cleansed of contaminating groups. The sociologist Zygmunt Bauman invokes the metaphor of the gardener to capture this phenomenon: the gardener who selects and uproots weeds to allow other plants to flourish (Bauman, 1989: 91–93). Aly and Roth (cited in Sünker and Otto, 1997: 22) summarize the NS project thus: "the 'final solution to the Jewish issue' was part of a 'final solution' to the social issue." Reducing the population to a desirable *Volk* community had the secondary benefit of cutting the welfare budget so that funds could be diverted to nation building. So, how were social workers enmeshed in this cruel project?

When Stefan Schnurr (1997: 127–128) interviewed former social workers who had served under the NS regime, he found that they put forward apologetics centered on the defense of 'professionality.' They all said they did not like Nazism but were able to exploit its spaces. Here is one testimony:

> Although you did receive training at the *Gauschule*, you just didn't listen to what they were saying, right? The important thing was the commitment to people, to the mothers whom I had got to know in the factories [the speaker's previous field of work], and I knew that they urgently needed something where they would gain recognition, where they could get answers to their questions, and so on. And that is why I went into it positively.

Doing 'good' remained a possibility and a defense for this practitioner. He pleaded ignorance: "it was a long time before I heard about these negative things" (Schnurr, 1997: 128). This plea was in tension with the explicit duties placed on social workers to assist in population selection. Another former social worker presented her participation in the sorting process as a 'neutral administrative act' (Schnurr, 1997: 134),

> And among my clients, I was also a social worker for the health department, I knew a whole lot, a whole lot, well, more than two hands-full, you know, who were suffering from hereditary diseases. And I had to make a note of that. So I wrote down their names for my medical officer. There was no other way at the time. Because he has also had to produce something and was not a fervent National Socialist.
>
> Schnurr, 1997: 132

Such dissociation from the actuality of the task recalls Bauman's discussion of the role of 'distantiation' and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28005-7

'differentiation' in the administration of the Holocaust (Bauman, 1989: 98–102). By representing the list compilation in this fashion, this woman's retrospective account can hardly be judged to be reflexive. However, the predicament of social workers had to do with their specific positionality between state and client in public and private institutions. It was a predicament shared with other professionals – teachers, lawyers, judges, and doctors.

Many social workers played a critical role in the eugenic policies of National Socialism precisely because they were strategically placed in prisons, children's homes, reform schools, maternity wards, and family homes. They were able to support the sorting, selection, and ultimately sterilization and slaughter of those labeled disturbed, disabled, dangerous, or racially impure. Waaldijk (2011) writes that social workers' expertise in classifying individuals and families as worthy or unworthy during this period helped prepare the ground for genocide, even if their collaboration did not require positive adherence to NS ideals. From the testimonies, Schnurr gathered, many social workers were contemptuous of what they saw as "the boundless stupidity of the NS officials who did not understand anything about our work" (Schnurr, 1997: 133). This posture enabled professional distancing from the cruelties that accompanied this perceived stupidity. Schnurr concludes that adherence to National Socialism was not a condition of collusion with its aims. Collusion simply required the demarcation of a professional space – one in which it could be claimed that allegiance to the client was the prime determinant of actions and in which compliance with partial, demarcated tasks was dissociated from their functionality for genocide. Social workers, like everyone else, created masks for themselves and even after some distance from the past, following Schnurr's discussion in the 1990s with a group of social workers who had practiced under National Socialism, they could not lift the masks.

Dealing with the Past

As Sünker and Otto (1997) and Waaldijk (2011) stress, the collusion of social workers should not be treated as a closed episode but rather absorbed into the profession's sense of its own formative history. So too, should stories of social workers who heroically refused to cooperate with the Nazi regime. While most people complied, there were some who did not and relied on their own sense of professional judgment and common humanity. They could not do what they were instructed to do. We might call this, following Theodor Adorno, the 'primal phenomenon of moral behavior' that occurs when "the element of impulse joins forces with the element of consciousness to bring about a spontaneous act" (Adorno, 2006: 240). Johnson and Moorhead (2011) recount some inspiring examples, like that of Alice Salomon, one of the founders of German social work, who advocated peace, disarmament, and women's rights. She was deprived of her doctorate, which was one of the first studies of women at that time, and was ultimately expelled from Germany. The scale of compliance and collaboration of the social work profession with National Socialism has been the cause for reflection on the purpose and ethical foundation of social work practice and policy. It has become a profession now anxious to get it right, having once got it so horribly wrong.

In his survey of social work practice, Waadjik summarizes the profession's relation to the past in an interesting way,

> Social workers operate daily in societies shaped by the disasters and by the triumphs of the past, they work with clients whose lives, whose parents' lives and whose expectations are shaped by this past. In order to provide assistance to these clients, it is crucial that social workers are aware of the way their own professional ideals and practices have been shaped by these pasts as well… Social workers have in different circumstances behaved differently, some resisted, other assisted racist political regimes. Some were cogs in a machine of repression; others combined social work with struggles for survival, liberation and freedom. The remains of these choices continue to play a role in professional ideals – we'd better address them.
>
> Waaldijk, 2011

This self-aware and self-critical account of the profession's relation to its own past may be contrasted with the idealized accounts found in official statements of the profession, such as the *International Definition of Social Work* (presently under consultation) supported by the International Association for the Schools of Social Work (IASSW) and International Federation of Social Workers (IFSW, 2012b). It offers an altogether rosier version of the profession's formative history:

> Social work grew out of humanitarian and democratic ideals, and its values are based on respect for the equality, worth, and dignity of all people. Since its beginnings over a century ago, social work practice has focused on meeting human needs and developing human potential. Human rights and social justice serve as the motivation and justification for social work action. In solidarity with those who are disadvantaged, the profession strives to alleviate poverty and to liberate vulnerable and oppressed people in order to promote social inclusion. Social work values are embodied in the profession's national and international codes of ethics.
>
> IASSW, 2012

This international definition of social work exemplifies what Sünker and Otto refer to as "a mentality of repression" in the profession:

> Social work is today still largely disinterested in what it has inherited from NS … In this sense it moves within the same spectrum of mentalities of repression as other professions and disciplines.
>
> Sünker and Otto, 1997: 144

The choices made by German social workers in this dreadful period are not so much addressed as glossed over. This glossing of the past applies to other episodes of complicity in oppressive practices (Dominelli, 2002).

The Ethical Turn

Rather than address their highly equivocal *past*, the professional bodies of social work turned to ethical guidelines to shape *future* practice. There is general recognition that 'the loyalty of

social workers is often in the middle of conflicting interests' and that 'social workers function as both helpers and controllers.' The tension social workers face between help and control is handled through explicit commitments to human rights and professional responsibilities. For example, there is a statement of "responsibility to challenge negative discrimination on the basis of characteristics such as ability, age, culture, gender or sex, marital status, socio-economic status, political opinions, skin colour, racial or other physical characteristics, sexual orientation, or spiritual beliefs" (IFSW, 2012a). A duty is placed on social workers to "bring to the attention of their employers, policy makers, politicians and the general public situations where resources are inadequate or where distribution of resources, policies, and practices are oppressive, unfair or harmful" (IFSW, 2012a). Absent, is any confrontation with the historical failure of many social workers to live up to these responsibilities and/or perform these duties. The IASSW-IFSW Global Standards document (2012), currently under revision, mentions pressures toward complicity with apartheid policies once imposed on social work educators in South Africa, and states that the profession resisted these pressures. Nonetheless, the orientation of this document, like that of the others, is to the future. This is not in itself a problem but it risks displacing an ugly history of malpractice. Here the deployment of the future tense tends to repress that of the past.

It is noteworthy that there is no mention of antisemitism in these mission statements. The professional organizations align themselves to the *Convention on the elimination of all forms of racial discrimination* (1969), which declares inter alia that "any doctrine of superiority based on racial differentiation is scientifically false, morally condemnable, socially unjust and dangerous, and that there is no justification for racial discrimination, in theory or in practice, anywhere." There is no explicit mention of antisemitism but rather a reliance on the expression 'all forms of racism.' This has the advantage of not having to list categories of vulnerable groups – lists that inevitably exclude some groups and invite argument about which categories should be included. Yet, a question remains as to what is read into 'all forms of racism' and the place of antisemitism within this frame. We put this question because, if the notion of racism in social work as with other public services is associated with racism against groups suffering from social and economic discrimination, an unintended consequence of this approach may be to make invisible forms of antisemitism that do not fit into this frame. Some multicultural practices have included a concern with faith, including Judaism, which makes an antiracist contribution in terms of respect and tolerance for diverse faith communities, but this emphasis does not address other troubling and difficult forms of antisemitism (Levine, 2004; Sicher, 2009).

The invisibility of antisemitism can be discerned in the practices of ethnic monitoring in public institutions, which arrived in the UK from the US during the 1970s. Its purpose was to produce statistical evidence of access to social goods by ethnic group on which to make judgments about where discrimination might be occurring. This purpose stands on its head the kind of 'ethnic monitoring' characteristic of Nazism. A concession to those for whom ethnic monitoring continues to be a reminder of a sinister past, has been the addition of a 'prefer not to say' box – now largely replaced with a box marked 'Other.' Regardless of good intentions, the textual silence regarding antisemitism remains. This textual silence may create awkwardness for Jewish individuals, but more importantly, it may withhold recognition of the weight of the past on the present, thus presenting a tension. On the one hand, there is something troubling about omitting any specific mention of antisemitism from the language of antiracist ethics and ethnic monitoring. On the other hand, 'counting Jews' is part of the repertoire of the antisemite whose refrain is that Jews are overrepresented in places of control and privilege. The motive force behind contemporary ethnic monitoring is about underrepresentation of minorities, but this may be reversed if it becomes associated with suspicion of overrepresentation.

Reports of a curious incident in a Department of Social Work at Toronto University may illustrate the problem (Lightman, 2010). Some 'visible minority' students expressed discomfort at having to participate in a placement at a pioneering nursing home as part of their study and said they felt threatened by 'so many rich Jews.' The Professor to whom these objections were expressed is reported to have been sympathetic to this view and permitted the students to conduct a 'Jew count' of Jewish benefactors to the University as a marker of their undue influence. Complaints were made and as far as we know quietly resolved, but it is troubling that the students' discomfort over learning from 'rich Jews' was not itself more discomforting to some of the department's academics. We should not place too much weight on one contested incident, but it illustrates how antisemitic threads from the past can reemerge.

Social work has an ugly past regarding antisemitism. As Waaldijk (2011) urges, this past has to be addressed to understand how it reverberates in the present. The creation of universalistic and forward-looking ethical frameworks goes some way to addressing the problem but does not name the past. It condemns racial discrimination but does not explore why it happened once and could happen again.

Connecting and Disconnecting Antisemitism

There has been a tendency to present our age as having radically broken from the conditions of life that gave rise to antisemitism in the past, to give the story of European antisemitism a happy ending, and to say that other kinds of racism now existing in Europe – notably against Muslims, immigrants, and Roma – have replaced antisemitism (Beller, 2007; Bunzl, 2007). This tendency is underwritten by shifting representations of Jews in the post-Holocaust world: as part of the European white elite, and as victimizers of Palestinians. The effect of this shift is to render incidents of antisemitic hate speech, abuse, and violence more amenable to other interpretations – from allusions to Jewish oversensitivity to displacing the onus of responsibility onto the actions of Jews themselves (Community Security Trust, 2010).

Antisemitism has not simply vanished in the new, post-Holocaust Europe (Judt, 2007). Many scholars now reject the 'eternal antisemitism' approach, in which antisemitism appears as a permanent and natural feature of relations between Jews and non-Jews (Arendt, 2004: 7). However, the answer to an ahistorical frame of reference that eternizes antisemitism is not to turn it on its head and confine antisemitism to history, but to

explore the ways in which the forces that created antisemitism in the past may persist in the present. Antisemitism in the past provided an epistemic framework to explain social pathologies from defeat in wars to financial crises; this epistemic function persists into the present (Julius, 2010: 54–59, 483–488; Nirenberg, 2013; Jacobs, 2011). As Naomi Klein has written,

> [E]very time I log on to activist news sites like Indymedia.org which practise 'open publishing', I am confronted with a string of Jewish conspiracy theories about September 11 and excerpts from the "*Protocols of the Elders of Zion*".
>
> Klein cited in Jacobs, 2005

Old antisemitic typifications of 'the Jews' – that Jews are indifferent to the suffering of others, treacherous toward their host countries, protective of their own exclusive interests, and incapable of genuine universality – create racist myths parallel to those that claim the incapacity of black people to achieve moral or intellectual maturity or the incapacity of Muslim men to treat women as equals or to understand human rights (Finkielkraut, 2001: 46–53). The content of these typifications is different – Jews tend to be typified as bearers of an intellectually distorted modernity, black people as bearers of premodern savagery, Muslims as bearers of an antagonistic civilization – but in all cases, racism represents the same human bankruptcy.

The disconnection of antisemitism from racism has not been total (notable exceptions are Gilroy, 2001; Lapierre, 2011; Sundquist, 2005), but where it exists it has created significant difficulties of understanding. In the postwar period, professionals have tended to focus on the social disadvantages and discriminations suffered by black immigrants and their descendants. This focus has shown its worth by contributing to the amelioration of social conditions faced by them and the formation of a more inclusive democracy. However, the Jews who survived after the Holocaust have not figured strongly in this framework. Other factors also contributed to the disconnection of racism and antisemitism. These include the imperatives of intellectual specialism, where the largely separate development of Postcolonial and Holocaust Studies has engendered fruitful research in their respective areas but at the cost of constructing disconnected frames of analysis, and the emergence in some urban situations of antagonism between black and Jewish social actors that has served to naturalize their separation (Altglas, 2012; Cousin and Fine, 2012). The difficulties of sustaining the connectivity of racism and antisemitism can be exemplified in relations between two contemporary academic discourses: 'critical race theories' (Delgado and Stefancic, 2011) and 'new antisemitism theories' (for an overview see Judaken, 2008). Each represents a collective endeavor to recognize and resist 'new' forms of racism and antisemitism, which wear the masks of liberalism, radicalism, or even antiracism. While the strength of these theories has been to draw attention to covert and subtle forms of prejudice, the downside is to see racism and antisemitism, respectively as exclusive and ubiquitous (Fine, 2009).

The concern expressed by proponents of 'new antisemitism theory' is that antisemitism has entered into the depiction of Israel as a uniquely illegitimate state, Zionism as a uniquely noxious ideology, supporters of Israel as a uniquely powerful lobby, and memory of the Holocaust as a uniquely self-serving reference to the past (MacShane, 2008; Harrison, 2006; Hirsh, 2007). Behind what passes as 'criticism' of Israel, the fear is that there sometimes lurks a reconstruction of old antisemitic typifications in a new guise: blood libel (the charge that Jews murdered Christian children for their blood), global conspiracy, and indifference to the suffering of others. The fear is that antisemitism is being mediated through forms of political criticism of Israel and Jewish nationalism, whose premise is that 'the Jews should know better' and that a particular burden of moral responsibility rests on 'the Jews.'

Critics of new antisemitism theory (Karpf et al., 2008; Klug, 2004; Rose, 2005) have argued inversely that behind the charge of antisemitism lies an unwillingness to face up the human rights abuses committed by the Israeli state. The fear is that the value of the term 'antisemitism' is debased by its political misuse, and that it is being misused to stigmatize those who express solidarity with Palestinians. For these critics, concern over antisemitism is portrayed as a dishonest way of justifying the unjustifiable: the ethnic character of the Jewish state. In this vein, the Marxist philosopher, Alain Badiou has argued that the signifier 'Jew' is now used as the sign of a victim ideology which places Jews beyond reproach, renders invisible other racisms, declares that Israeli crimes must be tolerated, and accuses those who do not tolerate them (like Badiou himself) of antisemitism (Badiou, 2011). He and his coauthor maintain that, because an ethnically defined state can no longer be defended openly and honestly, Israel's defenders resort to the charge of 'antisemitism' to defend it covertly and dishonestly (Badiou and Hazan, 2011). Badiou treats new antisemitism theory not as an expression of concern over the reemergence of antisemitism, but as the signifier of a reactive consciousness that is on the side not only of Israel against Palestinians but also of all repressive, occupying powers against popular resistance.

Badiou's polemic entrenches the disconnection of antisemitism from other racisms. In order to construct a consistent antiracism, however, it is vital to deconstruct the terms of this debate. To this end we offer three observations. First, it should be no more controversial to say that *some* criticism of Israel is antisemitic than to say that *some* criticism of India or Zimbabwe is racist or that some criticism of Iran or Saudi Arabia is Islamophobic. We learn to distinguish between 'orientalist' and legitimate forms of criticism in all cases (Sen, 2006). In relation to criticism of Israel in particular, the European Union Monitoring Commission (2005) has put forward guidelines designed to inform judgment of when criticism of Israel is or is not antisemitic. It maintains, for example, that when criticism of the Israeli government is like criticism of any other government, it is not to be treated as antisemitic, but that criticism of Israel can, depending on context, become antisemitic through the use of certain prejudicial arguments: (1) the Nazification of Israel (e.g., stating that Jews treat Palestinians like the Nazis treated the Jews), (2) the pathologization of Jews (e.g., claiming that Jews have become indifferent to the suffering of other peoples), (3) the use of old antisemitic tropes (e.g., asserting that Zionists engage in a world conspiracy to protect Israel or that Israeli forces steal Arab body parts), (4) the erasure of the distinction between state and civil society (e.g., saying that all Jews in Israel are responsible for the policies pursued by the

government), or (5) systematic treatment of Israel as culpable by standards not applied equally to other states. As the title 'working definition of antisemitism' suggests, these guidelines are presented as provisional, not final (Klug, 2004).

Second, both within new antisemitism theory and critical race theory there has arisen a temptation to treat the other as an adversary and homogenize and stereotype its views: for example, to declare that new antisemitism theory is racist toward Muslims or that critical race theory is racist toward Jews. Behind these mutual recriminations, however, both bodies of thought address real and related problems: the new forms of racism and antisemitism that have emerged in modern times but do not speak their name.

Third, there is a professional and moral obligation to take any charge of racism or antisemitism seriously. There are some who address racism and antisemitism from an exclusively 'national' point of view, and some who instrumentalize the charge of 'racism' and 'antisemitism' for their own economic or political ends. However, the ethical obligation is not to dismiss the problem of racism and antisemitism for these reasons. It is a paradox that those who criticize new antisemitism theory for its nationalism may nonetheless hold the view that the nationalism of the oppressed is in general an appropriate way to combat racism. To slip from a general critique of exclusivity in antiracist struggles to the critique of new antisemitism theory as the embodiment of exclusivity has specific echoes of an old prejudice concerning the exclusivity of Jews (Hirsh, 2007).

Conclusion

All professionals, including social workers, have the responsibility critically to challenge a conception of compliance that accepts whatever happens to be a policy at a given time and place, including antisemitic policies. To recognize antisemitism requires thought and understanding. This involves questioning the common sense notion that antisemitism is so readily identifiable as contrary to antidiscrimination policies that there is no further need to become reflective about what it is (Sartre, 1995). It is not enough simply to look inward to ask if one's own actions or motives are antisemitic. This brief survey suggests the importance of reflecting on the lessons of a past in which there was compliance with antisemitic policies, and hearing the voices of those who feel themselves to be subjected to discrimination without prejudging the validity of their claims (Gidley, 2011). To this end we have urged increased connectivity between our understandings of racism and antisemitism, which have their own distinctive characteristics but are best understood in relation to one another.

Antisocial Behavior

Stephen Crossley, Durham University, Durham, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Issues of 'deviance,' 'delinquency,' 'disorder,' and 'incivilities' have occupied politicians and policy makers for many years. The current widespread policy focus on 'antisocial behavior' draws heavily on theories, which advocate early intervention for low-level nuisance and disorder, to break perceived links with more serious subsequent criminal behavior. This 'widening of the net' of forms of social control associated with these issues has necessitated that social workers curb the behavior of alleged unruly people. This control function potentially places practitioners at odds with widely held social work ethics and value and has implications for social work practice and education.

> Sociology tended to rest heavily upon the idea that deviance leads to social control. I have come to believe that the reverse idea, i.e. social control leads to deviance, is equally tenable and the potentially richer premise for studying deviance in modern society.
> (Lemert, 1972: p. ix)

> What to some are the highest reaches of the welfare state are to others the furthest extension of social control.
> (Lipsky, 1980: p. 11)

Introduction

Issues such as 'deviance,' 'delinquency,' 'disorder,' 'incivilities,' and 'nuisance' have occupied theorists, researchers, politicians, and policy makers for many years. In 1959, Barbara Wootton suggested that:

> No-one can embark on a discussion of antisocial behavior (ASB) without making assumptions as to the criteria by which any specific actions are defined as such; and those assumptions are bound to reflect, not only the norms of a particular culture, but in some degree also, the subjective preferences of the person who makes them. What is understood to be unacceptable behavior varies from place to place and from time to time; and even where standards are much the same, actual manifestations will vary.
> (Wootton, 1959: p. 13)

This article explores some of these concerns in more detail, beginning with what antisocial behavior (ASB) is understood to involve at the current time and where its most recent origins can be found. The focus on ASB spreads across continents and some of the similarities and differences in approaches across cultures are also explored. The differences between them can be partly explained by the influence of wider social policies and welfare systems, which differ between countries and which themselves are borne out of different political and economic visions and circumstances. The withdrawal from a wider social solidarity project to a narrower vision of maintaining order has implications for social work practice and these tensions are explored, making use of an extensive literature that highlights the competing roles that social workers are often asked to carry out. Examples are drawn from a number of different countries and from a wide range of sources to highlight the international and historical saliency of this policy area. However, the robust approach to ASB in the United Kingdom is utilized to examine some points in greater depth.

What Is ASB?

ASB is currently defined under UK law as "acting in a manner that causes or is likely to cause harassment, alarm or distress to one or more persons not of the same household as the person" (Anti-Social Behaviour Act, 2003: p. 26). A new ASB, Crime, and Policing Bill introduced to the UK Parliament in 2013 includes proposals covering a wide range of areas, including dangerous dogs, firearms offences, forced marriage, policing reforms, extradition, and criminal justice, as well as ASB. It is perhaps not surprising, therefore, that this 'version' of 'ASB' has encountered some criticism for the breadth of its coverage. Burney has called it an "elastic concept" (2005: p. 7) and a "hydra-headed monster" (p. 16) while Ashworth has suggested it as "a vague term with a broad definition, which in the last few years has become a rallying call for some onerous and intrusive measures against individuals" (2004: p. 263).

The history of the concept of ASB and related terms has been covered extensively elsewhere (see, e.g., Morris, 1994; Burney, 2005; Welshman, 2006; for histories relevant to the United Kingdom). It is, however, notable that there are some strong similarities between the current focus on 'ASB' and previous historical social concerns about the behavior and/or depravity of certain social groupings. For example, it has been suggested that the contemporary media and political concern surrounding ASB hold a number of similarities, in both application and appeal, to the widespread public anxiety about the so-called dangerous classes in Victorian times (Burney, 2005; Morris, 1994) and it has been argued that these concerns tend to be periodic (Cohen, 2002).

The present focus on low-level nuisance and disorder owes much to the 'Broken Windows' thesis, which originated in the United States (Kelling and Wilson, 1982) and the accompanying policy response of 'zero-tolerance policing,' which was credited with being the primary factor in a significant reduction of crime and nuisance behavior in New York. Kelling and Wilson suggest that there is general agreement between social psychologists and police officers that if a broken window is left unrepaired for a period of time, other windows will get broken as well. These authors argue that 'because some areas are

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28006-9

inhabited by determined window breakers,' people are not only fearful of a sudden, violent attack in public places, they are also fearful of:

> being bothered by disorderly people. Not violent people, nor, necessarily, criminals, but disreputable or obstreperous or unpredictable people: panhandlers, drunks, addicts, rowdy teenagers, prostitutes, loiterers, the mentally disturbed.
> (Kelling and Wilson, 1982: p. 1)

The need to 'maintain order' therefore becomes a policy priority. In this scenario, low-level nuisance cannot be left unchecked for fear of informal community controls breaking down and the precursory warning signals of more serious crime and disorder need 'nipping in the bud.' Despite a number of critics questioning this deterministic view, the concept has traveled well. Aided by wider processes of globalization, the neoliberal and international 'policy market' has helped to ensure that a number of different countries have adopted and adapted different aspects of the zero-tolerance approach to suit their own particular needs and systems.

Burney (2005) draws on a wide range of research to highlight a number of different examples from Europe, including Holland, Sweden, France, and Austria. While there are undoubtedly similarities between some of the policies and approaches used to tackle nuisance behavior, there are also differences. In the original Broken Windows article, Kelling and Wilson note that the majority of the foot patrol officers are white while the 'people on the street' were usually black. These people were then 'sorted' into 'regulars' who the police officers recognized and 'strangers,' who they did not know. The similarities with some countries on mainland Europe are apparent as racial tensions, immigration, and the perceived lack of integration of relatively new, predominantly Muslim communities (especially young men) that have been main drivers of new legislation in that continent. However, the primary target of extended ASB legislation in the United Kingdom has been white working class youths, stereotypically located in areas of industrial decline, deprivation, and unemployment (Burney, 2005: p. 162), although black and minority ethnic groups are overrepresented in penal establishments. Another marked difference between countries is the extent to which state agencies get involved and the way in which they do so. It has been noted, for example, by Burney (2005: p. 157) that Swedish welfare agencies will intervene early to offer support to families and that their system does not include 'purely negative' instruments such as the Antisocial Behavior Order (ASBO) (Anti-Social Behaviour Act, 2003: p. 62) that form part of the UK legislative arsenal. Burney also notes that there appears to be genuine surprise and bemusement among Swedish welfare agencies regarding the politically motivated deployment and 'reach' of ASB legislation in England and Wales.

It has been suggested that, in the United Kingdom, New Labour 'invented' ASB but others have instead proposed a 'rediscovery' of ASB. Drawing on the claim by a former Prime Minister, Tony Blair, Squires and Stephen argue that when he first used the phrase in 1988, "anti-social behaviour did not arise, perfectly formed, in the mind of this politician then. Rather, it reemerged as a result of a complex combination of influences" (Burney, 2005: p. 20) including a focus on social exclusion and victimization and the residualization of social housing. Tracing the development of the concept through the 1980s and 1990s, Squires and Stephen also highlight the 'Broken Windows' influence, and suggest that, by arguing for the need to break the links between juvenile delinquency and persistent adult criminality and 'intervene early,' Labour merely succeeded in strengthening already perceived links in the minds of the electorate. This move placed Labour in the center of the 'law and order' debate initiated earlier by the Conservative government, especially under Michael Howard as Home Secretary, about being 'tough' on law breakers, as it maneuvered for electoral success.

As Squires and Stephen note, the 'rediscovery' of the term 'ASB' fitted with the wider New Labour focus on 'social exclusion,' which was subsequently critiqued as a vague concept, which houses competing discourses (Levitas, 1998). The concept has also been useful in mobilizing communitarian government projects such as New Labour's Together and Respect Agendas, which called on 'active citizens' to utilize and develop their social capital and play a role in supporting state agencies to tackle ASB and instill the old fashioned virtue of respect in an apparently wayward younger generation.

The links between 'ASB' and 'social exclusion' highlight that criminal justice policies are not developed in isolation, away from other social and economic policies. David Garland has highlighted that "the same premises and purposes that transformed criminal justice are evident in the programmes of 'welfare reform' that have been adopted by governments (and opposition parties) on both sides of the Atlantic" (Garland, 2001: p. 196). He argues that the social democratic 'solidarity project' of the middle decades of the last century has given way to a "more reactionary, less ambitious one of reimposing control" (2001: p. 199). This has led to poor people and criminals being again "viewed as members of a culturally distinct and socially threatening 'underclass,' in which all of the pathologies of late modern life are concentrated" (2001: p. 196). Mobilizing the concept of 'othering' (see Lister, 2004 for a discussion on this specifically in relation to poverty), he argues that "so long as offenders and claimants appear as 'other,' and the chief source of their own misfortune, they offer occasions for the dominant classes to impose strict controls without giving up freedoms of their own" (2001: p. 198).

This 'labeling' of others as somehow different and, more usually, 'deviant' (Becker, 1963) has been extended, in the United Kingdom at least, from a focus primarily on ASB to include the other 'pathologies' that Garland alluded to, with a range of perceived familial failings identified as worthy of state intervention. This is most acutely demonstrated in policy programmes designed to 'tackle' 'troubled families' or 'families with multiple disadvantages,' in which ASB features prominently.

Following the riots in a small number of towns in England in 2011, something akin to a moral panic ensued and 120 000 families that had previously been identified as having 'multiple disadvantages' became known as 'troubled families,' with a large centrally organized programme operationalized

to 'turn their lives around.' The UK Prime Minister, David Cameron, stated that his 'mission in politics' was 'fixing the responsibility deficit,' almost perfectly articulating what Garland has called the "responsibilization strategy" (2001: p. 124). In launching the Troubled Families Programme, Cameron said:

> Officialdom might call them 'families with multiple disadvantages'. Some in the press might call them 'neighbours from hell'. Whatever you call them, we've known for years that a relatively small number of families are the source of a large proportion of the problems in society. Drug addiction. Alcohol abuse. Crime. A culture of disruption and irresponsibility that cascades through generations.
> (Cameron, 2011)

Critics of the Troubled Families Programme have noted that the original figure of 120 000 families was identified from a government report exploring families with multiple disadvantages, such as maternal mental health issues, low income, poor quality housing, and low parental skills or qualifications. However, the current group of 'troubled families' are identified as those that have an adult on out-of-work benefits, where children are not attending education and where crime and/or ASB is taking place. This highlights the view, as articulated by Cohen, that "The 'deprived' are not very different from 'the depraved'" (1985: p. 60).

Each 'troubled' family is allocated a 'keyworker' from a local state or voluntary sector welfare agency to help them 'turn their lives round,' with a strong emphasis on the importance of locally developed solutions, highlighted by a lack of statutory guidance supporting the programme. Drawing on the work of Cohen again, the Troubled Families Programme therefore represents a good example of a 'flexible system' where 'Crime and delinquency nets thus not only become blurred in themselves but get tangled up with other welfare, treatment and control nets.' Cohen goes on to suggest, perhaps unfairly, that, "In Britain, social workers are the most powerful human service professionals operating in these waters" (1985: p. 61).

Care or Control?

As I have noted above, the development of social policy does not take place in an intellectual or political vacuum and it therefore follows that these policies cannot be applied without consideration of broader social, economic, and political concerns. Policies need to be implemented – rules need enforcers – and social workers, in a broad sense, are the professionals tasked with implementing a range of social and welfare related policies. Tensions can, however, occur when professionals whose primary role is to ensure the welfare of their clients are tasked with carrying out the function of 'controlling' certain kinds of individuals or families and/or their behaviors.

In his classic work *The Policing of Families*, Jacques Donzelot (1997) argued that social workers were gradually taking over from teachers in civilizing members of society. He suggested that, although social workers are "scattered throughout a multiplicity of inscription sites" they focused on what he called the 'less favored' classes' and, more specifically:

> the pathology of children in its dual form: children in danger – those whose upbringing and education leaves something to be desired, and dangerous children, or delinquent minors.
> (Donzelot, 1997: p. 96)

Originally writing in 1977, Donzelot predicted the current focus on 'prevention' and 'early intervention' via an extensive state apparatus. He argued that so-called experts would look at delinquents' first encounters with state agencies, examine their families' backgrounds and then draw up a 'portrait' of their future life. Following this process of examination, "An infrastructure of prevention will then be erected around him (sic) and an educative machinery will be set into motion, a timely action capable of stopping him short of a criminal violation" (1997: p. 97).

This extension of the state apparatus and the corresponding increased interest in low-level nuisance has led to what Squires has called a "disciplinary welfare system" (1990: p. 1) where some of the tensions between the care and control functions of social policy – working 'with' families or working 'on' them – have become increasingly apparent. Drawing on Foucault's work around discipline and governmentality and Bentham's notion of a "disciplinary continuum" (1990: p. 49), Squires suggests that "a generalised terrain of social problems came to be the accepted target of a regime of state interventions" (Squires, 1990: p. 47) and that these interventions are increasingly being carried out by social workers.

This expansion and dispersal of discipline means that social workers themselves, who are often employed or funded by the state and therefore expected to carry out the functions of the state, have been drawn into potential roles in the disciplinary net (Cohen, 2002). These roles conflict with the original aims and the wider ethics and values of social work and have led to social workers being called "reluctant policemen" (Burney, 2005: p. 115). 'Russian dolls' enveloping an initial judicial state model (Donzelot, 1997: p. 98) and "agents of social control, disguised storm troopers of the state" (Cohen, 1985: p. 130). Bourdieu argues, somewhat more sympathetically that these 'minor civil servants' have work "shot through with the contradictions of the state" (Bourdieu, 1999: p. 184). They become the left hand of the state "whose right hand no longer knows, or worse, no longer wants, what the left hand is doing" (Bourdieu, 1999: p. 183).

In his book *The Deviant Imagination*, Pearson (1975) explores the 'ambiguous politics of social work' in more detail and refers to social workers as 'social policemen,' 'social tranquilizers' (1975: p. 133), and 'professional Robin Hoods' (p. 134) who take part in 'moral hustling' (Pearson, 1975: p. 136). He argues that attempts to 'start where the client is' risk ignoring the influence of the state in locating individuals in certain subject positions for 'the sake of administrative convenience' (Pearson, 1975: p. 128). The nature of a 'dual commitment' to society as well as the individual is explored and this commitment and accountability to a wider 'society' is, according to Pearson, poorly articulated by the social work profession.

Using more robust language, Pearson goes on to argue that:

> Social work perpetually dithers about whether it represents the technical business of deviance-control, or some kind of artistic enterprise built on faith.
> (Pearson, 1975: pp. 129–130)

> These ambiguities mirror social work's ambiguous relationship to social and political structure, and the question of whether social work represents a personal counselling service for active, free willed human agents or a mopping up operation for society's 'dregs'.
> (Pearson, 1975: p. 130)

These views, articulated in the 1970s are still relevant today. If we return to the UK example of the Troubled Families Programme, similar tensions become apparent. Social workers in the United Kingdom have been accused by Ministers and senior civil servants of colluding with families who are allegedly 'fluent in social work,' or of being 'politically correct' and 'naïve' when highlighting poverty as an issue when dealing with behavioral problems. They have been portrayed as lacking authoritative challenge and numerous high profile child protection cases and reports have highlighted 'missed opportunities' for 'intervention' by a range of welfare agencies, usually with a strong focus on children's services (see, e.g., Munro, 2011). Social workers have been made aware of the potential to use 'sanctions' such as having children removed into care, withdrawal of benefits and eviction from homes. In a speech to the Association of Police and Crime Commissioners in 2013, the Secretary of State for Communities, Eric Pickles said:

> And the challenging, authoritative voice of the police is crucial. Some of the most successful family intervention projects are those where the police are heavily involved. Because sometimes it's only when a family is truly confronted with consequences - whether that's the threat of eviction, of having kids taken into care, or criminal proceedings - that they start taking things seriously.
> (Pickles, 2013)

In this political climate, it is understandable that social workers often feel compelled to carry out the wishes of the state without critically challenging or engaging with the policies they are operationalizing. However, the tensions between the need to care for certain groups and the need to control the behavior of some, sometimes overlapping, groups do not just exist between a centralized state and a localized delivery workforce. Tensions and differences in approach can be found within and between various local agencies tasked with participating in multiagency approaches to tackling ASB. Managers within these services are sometimes viewed as being overly bureaucratic and unsympathetic to the complexities of frontline social work. However, the main tensions often arise between services tasked with working together on ASB issues, which often include housing providers, children's services, neighborhood wardens, environmental officers, education professionals, and representatives from probation and criminal justice agencies.

Drawing again on UK examples, recent work has highlighted some of the problems of the 'multiagency' and 'partnership' approaches to tackling ASB. Burney (2005) has indicated the difference that demography, geography, and history can play in localized approaches to ASB, while Matthews and Briggs (2008) have noted the varying levels of significance attached to different forms of ASB by different agencies and organizations. In a study of the approaches used by local Crime and Disorder Reduction Partnerships in three different areas in the United Kingdom, they identify two primary divisions: the first being between the community safety teams and housing departments and the second being between what were loosely defined as enforcement and welfare or caring agencies. They argue that there are "pronounced differences in the attitudes toward ASB among youth services, social services, and education departments on the one hand and the police on the other" (Matthews and Briggs, 2008: p. 93). These different attitudes often led to frustrations with the approach of some of the partner organizations, with police often viewed as being 'heavy handed' and unsympathetic and welfare and social workers being perceived as too soft and potentially obstructive to enforcement action being taken against individuals.

Edwards and Hughes (2008: p. 67) have argued that such differences lead to the brokering of 'satisficing' deals between the various agencies that recognize the 'various statutory, occupational, and populist pressures to which they are subject.' In some cases these deals have not been achieved and Edwards and Hughes note that, as a result of competing statutory duties for different agencies, the issuing of ASBOs has been challenged by some local authority social services departments 'as counter to the welfare of those children subject to these orders and, therefore, in contravention of section 1 of the 1989 Children Act' (Edwards and Hughes, 2008: p. 67).

Similar tensions can also be found in other countries where social workers are caught up in the expectations of local citizens and the policy responses identified by politicians and policy makers. The Netherlands has been highlighted as an example where a strategy of 'responsibilization' (Garland, 2001) has also been implemented with different public bodies expected to play their part in tackling crime and nuisance. The traditional view of Dutch society as tolerant and lenient has been contrasted with a tougher approach increasingly concerned with perceived deviation from Dutch norms and standards and which has argued that "social workers should focus on social cohesion and diversion of juveniles from the street – so participating with police to reduce feelings of insecurity and promote social control" (Burney, 2005: p. 146).

Implications for Practice

The potential for social workers to have 'split personalities' has been extensively documented and there is often a disconnection between the values and ethics associated with social work and the functions they are asked to carry out in everyday practice. The International Association of Schools of Social Work (IASSW) and the International Federation of Social Work (IFSW) state that the profession "promotes social change, problem solving in human relationships and the empowerment and liberation of people to enhance well-being." It goes on to define the ethics of social work as "based on respect for the equality, worth, and dignity of all people," "focused on meeting human needs and developing human potential" and states that "In solidarity with

those who are disadvantaged, the profession strives to alleviate poverty and to liberate vulnerable and oppressed people in order to promote social inclusion" (IFSW, 2013).

The IASSW and the IFSW recognize that social workers act as both helpers and controllers and these values, as we have seen, are often forced to 'compete' or 'collaborate' with the goals and aims of other parts of the state, especially when 'multiagency' approaches are lauded as the most effective way of delivering public services. Far from helping individuals to flourish and reach their full potential, social workers are often expected to help curb behavior that is viewed as unacceptable by the state, often among already disadvantaged and marginalized groups. Drawing on examples from Australian settings, Briskman has highlighted how these competing accountabilities can sometime lead to social workers implementing dominant and repressive policies. She argues that "A benign acceptance of practice norms can take hold, with social workers focusing on 'doing good' without critically reflecting on underlying ideologies that perpetuate inequalities and injustices" (Briskman, 2013: p. 51). Briskman advocates a 'dual loyalty continuum' as an explanatory framework for negotiating the opposing roles of control agent and care agent.

The 'dual loyalty continuum' highlights the shifting and dynamic nature of much of social work. The deep complexities of social work ensure that workers are constantly engaged in negotiating processes with clients and their families, colleagues within departments, and partners from other agencies. Depending on how their work with service users is progressing and the expectation or demands of fellow professionals, social workers will need to adopt different positions on this continuum and the question of care or control is not one which lends itself to an 'either – or' solution.

The concept of 'street-level bureaucrats' (Lipsky, 1980) is potentially useful in exploring the dilemmas faced by frontline workers. Lipsky highlights the room that social workers often have to maneuver and argues that most people 'encounter' government through their interactions with 'street-level bureaucrats' such as social workers, teachers, police officers, nurses, health visitors, and so on as opposed to more formal interactions with politicians and more senior bureaucrats in the traditional sense. These encounters are more frequent for poorer people as more affluent individuals and families can purchase private services in respect of health, education, housing, and other areas and there is consequently less of a perceived need to change or control their behavior as they are not seen as a drain on public resources. Lipsky (1980: p. 8) highlights that "the policy delivered by street-level bureaucrats is most often immediate and personal" and that decisions have implications for how people relate to and are perceived by their neighbors, and how they perceive and think of themselves:

> Clients of street-level bureaucrats respond angrily to real or perceived injustices, develop strategies to ingratiate themselves with works, act grateful and elated or sullen and passive in relation to street-level bureaucrats' decisions.
> (Lipsky, 1980: p. 9)

Despite an increasing interest in surveillance and control, opportunities do still exist that allow the left hand of the state to operate without the full knowledge or approval of the right hand, to use Bourdieu's analogy. Neoliberal discourses around 'freeing up' resources, 'local solutions,' and 'empowerment' provide space for social workers and street-level bureaucrats to develop alternative narratives, often with the support and inclusion of service users. Where marginalized individuals or groups struggle to have their voices heard by those in positions of authority, social workers can play a role in supporting them to do this and, where necessary, advocate on their behalf. This approach has long been recognized in relation to welfare support and advice from social workers but advocacy also takes place across different issues such as disability rights, legal advice and support, discriminatory practice, and so on. As was highlighted earlier, this role has been enacted in respect of ASB by some social service departments challenging the issuing of ASBOs through a legal process as it was viewed as being counter to the welfare of the children involved (Edwards and Hughes, 2008: p. 67).

As well as having considerable scope within the rules that they are expected to work within, Pearson (1975) has argued that bending or breaking the rules is the only way that social workers are often able to achieve the aims of their profession. He suggests that 'industrial deviance' is alive and well in the profession. Bartley (2006) has also carried out research in the United Kingdom that highlighted how welfare professionals who went above and beyond what was necessary for their job were highly valued by clients/service users and made a lasting and positive difference to their lives. However, she notes that:

> These were the exception, however, and when interviewed it was often the case that state welfare workers felt that their approach was despite their employing agency, rather than positively endorsed by the agency.
> (Bartley, 2006: p. 23)

The implications of these tensions extend beyond social work practice, and also resonate in the realms of social work education. Garrett has highlighted how, in the United Kingdom, government documents and reviews of social work practice have helped to focus on social work as a 'practical job' with little requirement for critical reflection and theoretical distractions, with 'learning by doing' prioritized over education time spent outside the workplace. Drawing on a wide range of academic work, he identifies the 'fallacy of theory-less practice' and argues that whether social work practitioners realize it or not, they are constantly drawing on and negotiating theories when carrying out their job (Garrett, 2013: pp. 2–3).

Educating social workers to adopt a critical stance in both their reading and their practice encourages them to see dominant or official discourses in different lights and may help them to understand what it may feel like to be a recipient of some social policies and interventions. This is certainly the case with an issue such as how best to 'deal with' ASB when, as Barbara Wotton (1959: p. 13) suggested over half a century ago, the study of this topic can often reveal as much about the rule makers as it does about the rule breakers.

Antitrust Policy: Lessons from the US

Daniel L Rubinfeld, University of California, Berkeley, Berkeley, CA, USA; and New York University, New York, NY, USA

Abstract

Whether applied through US, European, or other national competition laws, antitrust has come to represent an important competition policy instrument that underlies many countries' public policies toward business. As a set of instruments whose goal is to make markets operate more competitively, however, antitrust often comes into direct conflict with regulatory policies, including forms of price and output controls, antidumping laws, access limitations, and protectionist industrial policies. Courts in the US have widely adopted economic analysis as the theoretical foundation for evaluating antitrust concerns. Yet, antitrust statutes in the European Union also place heavy emphasis on the role of economics. This article provides a view of antitrust primarily from the perspective of the US policy; the review that follows illustrates a theme that has worldwide applicability. This article highlights: (1) the early antibig business period in the US, in which the structure of industry was paramount; (2) the period in which performance as well as structure was given significant weight, and there was a systematic attempt to balance the efficiency gains from concentration with the inefficiencies associated with possible anticompetitive behavior; and (3) the most recent period, which includes the growth of high technology and network industries, in which firm behavior has been given particular emphasis.

The term antitrust, which grew out of the US trust-busting policies of the late nineteenth century, developed over the twentieth century to connote a broad array of policies that affect competition. Whether applied through US, European, or other national competition laws, antitrust has come to represent an important competition policy instrument that underlies many countries' public policies toward business. As a set of instruments whose goal is to make markets operate more competitively, antitrust often comes into direct conflict with regulatory policies, including forms of price and output controls, antidumping laws, access limitations, and protectionist industrial policies.

Because its primary normative goal has been seen by most to be economically efficient, it should not be surprising that antitrust analysis relies heavily on the economics of industrial organization. But, other social sciences also contribute significantly to our understanding of antitrust. Analyses of the development of antitrust policy are in part historical in nature, and positive studies of the evolution of antitrust law (including analyses of lobbying and bureaucracy) often rely heavily on rational choice models of the politics of antitrust enforcement.

The relevance of other disciplines notwithstanding, there is widespread agreement about many of the important antitrust trade offs. Indeed, courts in the US have widely adopted economic analysis as the theoretical foundation for evaluating antitrust concerns. Interestingly, however, antitrust statutes in the European Union also place heavy emphasis on the role of economics. Indeed, a hypothetical conversation with a lawyer or an economist at a US competition authority (the Antitrust Division of the Department of Justice or the Federal Trade Commission (FTC)) or the European Union (The Competition Directorate) would be indistinguishable at first sight.

While this article provides a view of antitrust primarily from the perspective of the US policy, the article that follows illustrates a theme that has worldwide applicability. As our understanding of antitrust economics has grown throughout the past century, antitrust enforcement policies have also improved, albeit sometimes with a significant lag. In this survey the following are highlighted: (1) the early antibig business period in the US, in which the structure of industry was paramount; (2) the period in which performance as well as structure was given significant weight, and there was a systematic attempt to balance the efficiency gains from concentration with the inefficiencies associated with possible anticompetitive behavior; and (3) the most recent period, which includes the growth of high technology and network industries, and in which behavioral theories have been given particular emphasis.

The Antitrust Laws of the US

In the USA, as in most other countries, antitrust policies are codified in law and enforced by the judicial branch. Public cases may be brought under Federal law by the Antitrust Division of the Department of Justice, by the FTC, and/or by each of the 50-state attorneys general. (The state attorneys general may also bring cases under state law.) Further, there is a broad range of possibilities for private enforcement of the antitrust laws, which plays a particularly significant role in the USA.

The Sherman Act

Antitrust first became effective in the US near the end of the nineteenth century. Underlying the antitrust movement was the significant consolidation of industry that followed the Civil War. Following the war, large trusts emerged in industries such as railroads, petroleum, sugar, steel, and cotton. Concerns about the growth and abusive conduct of these combinations generated support for legislation that would restrict their power. The first antitrust law in the US – the Sherman Act – was promulgated in 1890. Section 1 of the Act prohibits: "Every contract, combination in the form of trust of otherwise, or

 http://dx.doi.org/10.1016/B978-0-08-097086-8.71010-5

conspiracy, in restraint of trade or commerce among the several states, or with foreign nations."

Section 2 of the Sherman Act states that it is illegal for any person to "…monopolize, or attempt to monopolize, or combine or conspire with any other person or persons, to monopolize any part of the trade or commerce among the several states, or with foreign nations…." These two sections of the Act contain the two central key principles of modern antitrust policy throughout the world – conduct that restrains trade and conduct that creates or maintains a monopoly – is deemed to be anticompetitive.

The Clayton Act

Early in the twentieth century, it became apparent that the Sherman Act did not adequately address combinations, such as mergers, that were likely to create unacceptably high levels of market power. In 1914, Congress passed the Clayton Act, which identified specific types of conduct that were believed to threaten competition. The Clayton Act also made illegal conduct whose effect "may be to substantially lessen competition or tend to create a monopoly in any line of commerce." Section 7 of the Clayton Act is the principal statute for governing merger activity – in principle Sect. 7 asks whether the increased concentration will harm actual and/or potential competition.

Other sections of the Clayton Act address particular types of conduct. Section 2, which was amended and replaced by Sect. 1 of the Robinson–Patman Act in 1936, prohibits price discrimination between different purchasers of the same type and quality of a commodity, except when such price differences are cost-justified, or if the lower price is necessary to meet competition.

Section 3 of the Clayton Act specifically prohibits certain agreements in which a product is sold only under the condition that the purchaser will not deal in the goods of a competitor. This Section has been used to challenge exclusive dealing arrangements (e.g., a distributor that is obligated to sell only the products of a particular manufacturer) and 'tied' sales (e.g., the sale of one product is conditioned on the buyer's purchase of another product from the same supplier). The Act does not prohibit all such arrangements – only those whose effect would be likely to substantially lessen competition in a particular line of commerce.

The FTC Act

The US is nearly unique among competition law countries in having two enforcement agencies. In part to counter the power granted to the Executive branch under the Sherman Act, Congress created the FTC in 1914. Section 5 of the FTC Act, which enables the FTC to challenge 'unfair' competition, can be applied to consumer protection as well as mergers. In addition, the FTC has the power to enforce the Clayton Act and the Robinson–Patman Act. While the agencies act independently of one another, the FTC and the Department of Justice's (DOJ) enforcement activities have generally been consistent with one another during most of enforcement history.

What then are the differences between the two enforcement agencies? A simple answer is that the FTC is responsible for consumer protection issues, whereas criminal violations of Sect. 1 of the Sherman Act (e.g., price fixing and market division) are the responsibility of the Antitrust Division. It is also important to note that most enforcement activities, when successful, lead to injunctive remedies, where the party that has violated the law is required to cease the harmful activity. Exceptions are the criminal fines that are assessed when Sect. 1 of the Sherman Act is criminally violated, and penalties that are assessed in certain consumer protection cases. Damages are rarely assessed by the federal agencies, otherwise, although have been exceptions in occasion (e.g., when the US represents the class of government employees or when disgorgement is deemed a necessary remedy).

The Goals of Antitrust

Despite considerable economic change in the economy over the twentieth century, the federal antitrust laws have continued to have wide applicability in part because their language was quite vague and flexible. This has led, quite naturally, to extensive historical study of the legislative history and substantial debate about congressional intent, especially where the Sherman Act is concerned. Some scholars have argued that the Sherman Act was directed almost entirely toward the achievement of allocative efficiency (e.g., Bork, 1966). Others have taken the view that Congress and the courts have expressed other values, ranging from a broad concern for fairness, to the protection of specific interest groups, or more simply to the welfare of consumers writ large (e.g., Schwartz, 1979; Stigler, 1985).

The debate concerning the goals of the antitrust laws continues today. The enforcement agencies, for example, evaluate mergers from both consumer welfare and total welfare (consumer plus business) points of view, in part because the courts are not clear as to which is the appropriate standard under the Clayton Act. While it seems clear that the Sherman Act was intended in part to protect consumers against the inefficiencies of monopolies and cartels, it is significant that at the time of the passage of the Act many economists were in opposition because they believed that large business entities would be more efficient. Whatever the goals of the Sherman Act, it is notable that a merger wave (1895–1905) soon followed the passage of the Act. It may be that outlawing various types of coordinated behavior (Sect. 1) may have encouraged legal coordination through merger.

Historical Developments

Because antitrust focuses on the protection of competitive markets, it was natural to suspect other nonstandard organizational forms as potentially anticompetitive. During the early part of the 1900s, most antitrust enforcement was public, and it was directed against cartels and trusts. Early successes included convictions against the Standard Oil Company (*Standard Oil v. United States*, 1911) and the tobacco trust for monopolization in 1911.

It is important to note, however, that the Sherman Act does not prohibit all restraints of trade – only those restraints that

are unreasonable. The distinction between reasonable and unreasonable restraints remains a subject of intense debate today. It is significant, however, that the distinction between per se analysis (in which a practice is deemed illegal on its face) and rule of reason (in which one trades off the procompetitive and anticompetitive aspects of a practice) was made during this early period, and it remains important today.

By its nature, a per se rule creates a rebuttal presumption of illegality once an appropriate set of facts is found. Per se rules have the advantage that they provide clear signals and involve minimal enforcement costs. Yet actual firm behavior in varying market contexts generates exceptions that call for in-depth analyses. It is not surprising, therefore, that the per se rule is the exception to the rule of reason norm.

An example of the application of rule of reason is price discrimination. Viewed as an exercise of monopoly power, the practice was seen as suspect. Indeed, the Robinson–Patman Act presumes that with barriers to entry, price discrimination marks a deviation from the competitive ideal that was presumed to have monopoly purpose and effect. Efficiency justifications for price discrimination and other 'restrictive practices' – promoting investment, better allocating scarce resources, and economizing on transaction costs – were overlooked during the early enforcement period. Confusion also arose between the goal of protecting competition and the practice of protecting competitors. At the beginning of the twenty-first century, however, efficiency arguments are clearly pertinent to the evaluation of Robinson–Patman claims.

There is no doubt that antitrust enforcement is difficult, even with the more sophisticated tools of industrial organization that are available today. The Sherman Act does not offer precise guidance to the courts in identifying illegal conduct. In both the Clayton Act and the Sherman Act, Congress has chosen not to enumerate the particular types of conduct that would violate the antitrust laws. Instead, Congress chose to state general principles, such as attempts to monopolize, and contracts or combinations that restrain trade, without elaborating on what actually qualifies for the illegal behavior. It was left to the courts to ascertain the intent of the antitrust statutes and to distinguish conduct that harms competition from conduct that does not.

In a significant early case, *Board of Trade of the City of Chicago v. USA* (1918), the Supreme Court reiterated the reasonableness standard for evaluating restraints of trade. The Court concluded that "The true test of legality is whether the restraint imposed is such as merely regulates and perhaps thereby promotes competition or whether it is such as may suppress or even destroy competition." In this and in subsequent cases, the court failed to provide a clear statement of when and how a rule of reason analysis should be applied.

Antitrust enforcement agencies and the courts continue to debate the mode of analysis that is most appropriate in particular market contexts and when particular practices are at issue. Both courts and agencies deem it appropriate to undertake some form of 'quick-look analysis,' one which goes beyond the application of a per se rule, but which falls short of a full rule of reason inquiry (see *California Dental Association v. FTC*, 1999, Melamed 1998). Per se rules are applied to certain horizontal restraints, involving two or more firms operating in the same line of business. Quick-look and rule of reason analyses are more prevalent when the restraints at issue are vertical (involving two or more related lines of business, e.g., a manufacturer and a supplier).

Quick-look and more complete rule of reason analyses have relied on a number of basic principles. First and foremost is the market power screen. Courts have appreciated that antitrust injury necessitates the exercise of market power. Antitrust analysis typically begins with the measurement of market share possessed by firms alleged to engage in anticompetitive conduct. As many scholars have noted (e.g., Stigler, 1964), in the absence of collusion, the exercise of market power in unconcentrated markets is unlikely. Market concentration is often seen as a necessary but not sufficient condition for the exercise of market power, since ease of entry, and demand and supply substitutability can limit the ability of firms to raise prices even in highly concentrated markets (e.g., Baumol et al., 1982). But, market concentration – market power screens are not essential; witness the Supreme Court's opinion in *Federal Trade Commission v. Indiana Federal of Dentists* (1986).

Although courts have long recognized the importance of market power to conclusions about antitrust injury, the standards by which they adjudicate antitrust cases, and their willingness to apply sophisticated economic analysis, have varied significantly over time. Antitrust policy once treated any deviation from the competitive ideal as having anticompetitive purpose and effect. Vertical arrangements were particularly suspicious if the parties agreed to restraint that limited reliance on market prices. Over time, however, the critique of such arrangements diminished as economists began to appreciate the importance of efficiencies associated with a range of contractual practices *Leegin v. OSKS* (vertical minimum resale price fixing); *Texaco, Inc. v. Dagher* (2006) (joint ventures).

The Structure-Conduct Interventionist Period

During the 1950s and the 1960s, the normative analysis of antitrust was dominated by the work of Joe Bain on barriers to entry, industry structure, and oligopoly (Bain, 1968). Bain's relatively interventionist philosophy was based on the view that scale economies were not important in many markets, that barriers to entry are often high and can be manipulated by dominant incumbent firms, and that supracompetitive monopolistic pricing is relatively prevalent. This tradition held, not surprisingly, that nonstandard and unfamiliar practices should be approached with skepticism. During this era, antitrust enforcers often concluded that restraints which limited the number of competitors in a market necessarily raised prices, and that the courts could protect anticompetitive conduct by appropriate rule making.

In this early structure-conduct era, industrial organization economists tended to see firms as shaped by their technology. Practices, such as joint ventures, that reshaped the boundaries of the firm (e.g., joint ventures) were often seen as suspect. Significant emphasis was placed on the presence or absence of barriers to entry, which provided the impetus for a very tight market power screen.

Because the government was often seen as benign, it was not surprising that antitrust looked critically at mergers and acquisitions. Moreover, in absence, a broader theory that encompassed a variety of business relationships among firms,

it is not surprising that the Supreme Court often supported government arguments without seriously evaluating the trade offs involved (e.g., *USA v. Von's Grocery Co.*, 1966).

Economies of scale are illustrative. That they can create a barrier to entry was emphasized under Bain's point of view, whereas the clear benefits that scale economies provide were given little recognition. For example, the Supreme Court argued that 'possible economies cannot be used as a defense to illegality' (*Federal Trade Commission v. Procter and Gamble Co.*, 1967).

Government hostility during this period also applied to markets with differentiated products. In *USA v. Arnold, Schwinn & Co.* (1907), for example, the government was critical of franchise restrictions that supported product differentiation because the restrictions were perceived to foster the purchase of inferior products at higher than competitive prices. The possibility that exclusive dealing was procompetitive was not given serious consideration during the 1950s and 1960s.

The failure of antitrust enforcers to appreciate the benefits of discriminatory contractual practices was also evident in the early enforcement of the Robinson–Patman Act. Through the 1960s, the Act was vigorously enforced. Legitimate reasons for discriminatory pricing were very narrow (e.g., economies of scale in production or distribution). Since the mid-1960s, however, there has been a significant shift. Fears that the Act might discourage procompetitive price discrimination have led to less aggressive enforcement by the FTC.

The 1960s and 1970s marked a period of substantial empirical analysis in antitrust, motivated by structural considerations. The literature on the correlation between profit rates and industry structure initially showed a weak positive correlation, suggesting that high concentration was likely to be the source of anticompetitive firm behavior. However, this interpretation was hotly disputed. If behavior that is described as a barrier to entry also served legitimate purposes, what can one conclude even if there is a positive correlation between profitability and concentration? The challenge to this line of empirical work is typified by the debate between Demsetz (1974) and Weiss (1974). Demsetz argued that concentration was a consequence of economies of scale and the growth of more efficient firms – in effect the early empirical work suffered from problems of simultaneity. If concentrated markets led to higher industry profits, these profits were the consequence and not the cause of the superior efficiency of large firms and they consequently are consistent with competitive behavior. Today, these early studies are viewed critically, as having omitted variables that account for research and development, advertising, and economies of scale. It is noteworthy that the observed positive correlation reflected both market power and efficiency, with the balance varying on a case-by-case basis.

The Influence of the Chicago School

All of the assumptions that underlie the tradition of the 1950s and 1960s came under increasing criticism during the 1970s, led in part by the influence of the Chicago School. While the views of its proponents (e.g., Posner, 1979; Easterbrook, 1984) are themselves both rich and varied, they have come to be typified as including the following: (1) a belief that the allocative efficiencies associated with economies of scale and scope are of paramount importance; (2) a belief that most markets are competitive, even if they contain a relatively few number of firms. Accordingly, even if price competition is reduced, other nonprice forms of competition will fill the gap; (3) a view that monopolies will not last forever. Accordingly, the high profits earned by dominant monopolistic firms will attract new entry that in most cases will replace the monopolist or at least erode its position of dominance; (4) a view that most barriers to entry, except perhaps those created by government, are not nearly as significant as once thought; (5) a belief that monopolistic firms have no incentive to facilitate or leverage their monopoly power in vertically related markets (the 'single monopoly rent' theory); (6) a view that most business organizations maximize profits; firms that do not, will not survive over time; and (7) a belief that even when markets generate anticompetitive outcomes, government intervention, which is itself less than perfect, is appropriate only when it improves economic efficiency.

The period of the late 1960s and 1970s not only marked a significant influence by the Chicago School; it also saw an upgrading of the role of economists in the antitrust enforcement agencies. The increased role continued through the end of the twentieth century in the US, as it did in the European Union. For example, two economists play decision-making roles at the Department of Justice – one a Deputy for Economics and the other a Director of Economic Enforcement (the FTC also has several economists in decision-making roles).

Because of the influence of the Chicago School, nonstandard contractual practices that were once denounced as anticompetitive and without a valid purpose were often seen as serving legitimate economic purposes. Not surprisingly, for example, the per se rule limiting exclusive distribution arrangements in *Schwinn* was struck down by the US Supreme Court in *GTE Sylvania, Inc. v. Continental TV, Inc.* (1977). Although the US DOJ/FTC Merger Guidelines does not explicitly spell out a trade-off analysis of efficiencies and competitive effects, accounting for the economic benefits of a merger is reflected in the Guidelines and is now standard practice. Antitrust enforcement is alert to trade-offs, and less ready to condemn conditions for which there is no obvious superior alternative.

The Post-Chicago School Analyses of Strategic Economic Behavior

In the 1970s and continuing through the 1990s new industrial organization tools, especially those using game-theoretic reasoning came into prominence. These tools allow economists to examine the ways in which established firms behave strategically in relation to their actual and potential rivals. The distinction between credible and noncredible threats, which was absent from the early entry barrier literature, has been important to an assessment of the ability of established firms to exclude competitors and to the implications of exclusionary conduct for economic welfare (e.g., Dixit, 1979). These theories also illuminated a broader scope for predatory pricing and predatory behavior. Previously scholars such as Robert Bork (1978) had argued that predatory pricing imposes high costs on the alleged predator and is unlikely to be profitable in all but extraordinary situations. Developments in the analysis of

strategic behavior provide a richer perspective on the scope for such conduct. Thus, nonprice competitive strategies that 'raise rivals' costs' (Krattenmaker and Salop, 1986; Ordover et al., 1990) are now thought to be quite prevalent. Indeed, models of dynamic strategic behavior highlight the ability and opportunity for firms to engage in coordinated actions and for firms to profit from conduct that excludes equally efficient rivals (e.g., Kreps and Wilson, 1982; Milgrom and Roberts, 1982).

The implications of the various models of strategic behavior remain hotly debated. On the more skeptical side is Franklin Fisher, who stresses that while these new developments offer insights, they are insufficiently complete to provide firm conclusions or to allow us to measure what will happen in particular cases (Fisher, 1989). A more optimistic view is given by Shapiro (1989) who believes that we can now analyze a much broader range of business competitive strategies than before. We also know much more about what to look for when we are studying areas such as investment in physical and intangible assets, the strategic control of information, network competition and standardization, and the competitive effects of mergers.

The analysis of strategic behavior has emphasized the potential for exercising market power, often to the detriment of consumers. At the same time, other analyses have stressed that there are gains to consumers from coordinated behavior among firms with market power. Thus, Coase (1937) argued that market forces were only one means to organize market activities, and that nonmarket organizations could provide a viable alternative. Further, Williamson (1985) developed the theory of nonmarket organization to show that contractual restraints can provide improved incentives for investments in human and physical assets that enhance the gains from trade. This transaction cost approach helps to provide a foundation for understanding the efficiency benefits of contractual restraints in vertical relationships.

Coupled with the game-theoretic analyses of firm behavior in imperfect markets has been the application of modern empirical methods for the analysis of firm practices. These newer methods allow for the more precise measurement of market power, and they indicate generally that market power is relatively common, even in markets without dominant firms (Baker and Rubinfeld, 1999).

The Public Choice Approach

Today, a balanced normative approach to antitrust would involve reflections on the broad set of efficiencies associated with various organizational forms and contractual relations, as well as the possibilities for anticompetitive strategic behavior in markets with or without dominant firms. A positive (descriptive) approach focuses on the relationship between market structure and the politics of the interest groups that are affected by that structure.

The theory of public choice has been used as the basis for limiting competitor standing to bring antitrust suits. In support is the argument that competitors' interests deviate from the public interest because competitors view efficiencies associated with alleged exclusionary practices to be harmful, and therefore are not in a position to distinguish efficient from inefficient practices. On the other hand, competitors are often the most knowledgeable advocates, and are likely to know more about the socially harmful effects of exclusionary practices long before consumers do. The debate over standing to sue has surfaced with respect to indirect purchaser suits (e.g., *Illinois Brick Co. v. Illinois*, 1977) and with respect to predatory pricing (*Brooke Group Ltd. v. Brown and Williamson Corp.*, 1993).

High Technology and Dynamic Network Industries

In the latter part of the twentieth century and continuing into the twenty-first, rapid changes in technology altered the nature of competition in many markets in ways that would most likely have surprised the antitrust reformers of the late nineteenth century. The early debates centered on scale – did the benefits of economies of scale in production outweigh the associated increase in market power? In many dynamic high technology industries today, demand, rather than supply is often the source of substantial consumer benefits and significant market power. Economies of scale on the demand side arise in industries such as computers and telecommunications because of the presence of network effects, whereby each individual's demand for a product is positively related to the usage of the product (and complementary products) by other individuals. Network effects apply to communications networks (where consumers value a large network of users with whom to communicate, such as compatible telephone systems and compatible fax machines), and they apply to virtual networks or hardware–software networks (where there is not necessarily any communication between users).

In industries in which network effects are significant, a host of issues challenges our traditional views of antitrust. Because network industries are often characterized by large sunk costs and very low marginal costs, there is a substantial likelihood that a successful firm will come to dominate a market and to persist in that dominance for a significant period of time. Indeed, while there is no assurance that a single standard will arise in network industries, it is nevertheless often the case that users will gravitate toward using compatible products. This combination of economic factors makes it possible for firms to adopt price and nonprice policies that exclude competition and effectively raise prices significantly above what they would be were there more competition in the market (Rubinfeld, 1998).

A host of hotly debated antitrust policy issues are raised by the increasing importance of dynamic network industries (Whinston, 2006). Whatever view one holds, there is little doubt that the antitrust enforcement stakes are raised. On the one hand, because the path of innovation today will significantly affect future product quality and price, the potential benefits of enforcement are huge. This perspective clearly motivated the Department of Justice and 20 states when they chose to sue Microsoft for a variety of antitrust violations in 1998 (*USA v. Microsoft*, 2001). On the other hand, because the path of innovation is highly uncertain and technology is rapidly changing, barriers to entry that seem great today could disappear tomorrow, and the potential costs of enforcement are large as well. The threat of potential entry by innovative firms was a significant part of Microsoft's defense in the Department of Justice case.

A related set of issues has arisen with respect to the overlap between intellectual property and antitrust. The law gives the owners of patents, copyrights, and other intellectual property monopoly rights over their property. But, what is the appropriate scope of those rights? When, if at all, should the owners of those rights be required to give access or otherwise deal with competitors (Carlton, 2001)? In its more expansive period, the Supreme Court had taken a rather broad view of those facilities that were deemed to be essential and required competitor access (*Aspen Skiing Co. v. Aspen Highlands Skiing Corp.*, 1985). But, over the past decade the Court has made it clear that it has little patience for the so-called essential facilities doctrine (*Verizon Communications v. Law Offices of Curtis v. Trinko*, 2004).

Standard Setting

In network industries, competitive problems may arise in the competition to develop market standards. Dominant firms may have an incentive to adopt competitive strategies that support a single standard by preventing the products of rivals from achieving compatibility. Indeed, when the dominant firm's product becomes the standard for the industry, firms that are developing alternative standards may find it difficult to compete effectively (Farrell and Katz, 1998). Alternatively, firms might collude to affect the outcome of the standard-setting (price-setting) process. Such collusion can be difficult to detect because firms often have procompetitive reasons for cooperating in the race to develop new technology. Indeed, firms often possess assets and skills that can make collaboration in developing a market standard an efficient arrangement. An example is the pooling of technology related to video and audio streaming on the Internet. In its business review letter of the MPEG (Moving Picture Experts Group)-II patent pooling agreement in 1997, the Antitrust Division of the Department of Justice spelled out a set of conditions under which the pooling of assets would be deemed to be procompetitive. Since that time, the Division has published a number of additional business review letters involving other patent pools (IEEE (Institute of Electrical and Electronics Engineers), 3G, DVD (Digital Video Disc)). Where and how to draw the line between procompetitive sharing of assets of skills and other anticompetitive activities that will discourage competitors in the battle for the next generation standard remains a highly significant antitrust issue (DOJ/FTC 2005).

As a general rule, one should expect that sufficient competition will exist to develop a new product or market standard whenever more than a few independent entities exist that can compete to develop the product or standard. This rule of thumb is consistent with case law and conclusions in guidelines published by the US antitrust authorities. For example, the DOJ/FTC *Antitrust Guidelines for the Licensing of Intellectual Property* concludes that mergers or other arrangements among actual or potential competitors are unlikely to have an adverse effect on competition in research and development if more than four independent entities have the capability and incentive to engage in similar R&D activity (DOJ/FTC 1995). Similarly, the 1984 DOJ/FTC *Merger Guidelines* (revised in 1992, 1997, and most recently in 2011) concludes that mergers among potential competitors are unlikely to raise antitrust concerns if there are more than a few other potential entrants that are similarly situated.

Leveraging

Leveraging occurs when a firm uses its advantage from operating in one market to gain an advantage in selling into one or more other, generally related markets. Leveraging by dominant firms in network industries may take place for a variety of reasons that can be procompetitive or anticompetitive, depending on the circumstances. The challenge for antitrust policy is to distinguish between the two. On the one hand, leveraging can be seen as a form of vertical integration, in which a firm may improve its distribution system, economize on information, and/or improve the quality of its products. Leveraging, however, can be anticompetitive if it serves as a mechanism by which a dominant firm is able to raise its rivals' costs of competing in the marketplace.

Leveraging can be accomplished by a variety of practices (e.g., tying, bundling, exclusive dealing), each of which may have anticompetitive or procompetitive aspects, or a combination of the two. For example, with tying, a firm conditions the purchase (or license) of one product – the tied product – on the purchase (or license) of another product – the tying product. A firm might choose a tying arrangement for procompetitive reasons, including cost savings and quality control. Suppose, for example, that a dominant firm offers to license its dominant technology only to those firms that agree to also license that firm's complementary product, and suppose that the complementary product builds on the firm's next generation technology. Such a tying arrangement could allow the dominant firm to create a new installed base of users of its next generation technology in a manner that would effectively foreclose the opportunities of competing firms to offer their products in the battle for the next generation technology (Farrell and Saloner, 1986). Alternatively, suppose that a dominant seller offers discounts to buyers that remain loyal to the seller by buying all or a substantial percentage of their product from that seller (*LePage's Inc. v. 3M*). In the extreme this could amount to an exclusive dealing arrangement, but short of that being fully exclusive, the practice could make it difficult for competitors to achieve adequate scale and ultimately be exclusionary (Melamed, 2005; Rubinfeld, 2005).

International Antitrust

The emergence of a global marketplace raises significant antitrust policy issues. On the one hand, free trade and the opening of markets makes it less likely that mergers will significantly decrease competition, and indeed, creates greater opportunities for merging or cooperating firms to generate substantial efficiencies. On the other hand, international price-fixing agreements are more difficult for US or other domestic enforcement agencies to police, since success often requires some degree of cooperation with foreign governments or international organizations. The 1990s we saw a significant increase in the prosecution of international price-fixing conspiracies. Indeed, from the late 1990s through the first decade of the twenty-first

century, the Department of Justice criminal fines received were in the hundreds of millions and occasionally billions of dollars from investigations that included vitamins and dynamic random access memory.

The internationalization of antitrust raises a host of difficult jurisdictional and implementation problems for all antitrust enforcement countries. One can get a sense of the enormous difficulties involved by looking at the problems from the perspective of the US. The Sherman Act clearly applies to all conduct, which has a substantial effect within the US. However, crucial evidence or culpable individuals or firms may be located outside the US. As a result, it is imperative for the US antitrust authorities to coordinate their activities with authorities abroad. This is accomplished in part through mutual assistance agreements, as, for example, in the agreement between the US and Australia under the International Enforcement Assistance Act. It is also accomplished through informal 'positive comity' arrangements, whereby if one country believes that its firms are being excluded from another's markets, it will conduct a preliminary analysis and then refer the matter to the foreign antitrust authority for further investigation, and, if appropriate, prosecution. (Such an agreement was reached with the EU in 1991.) Today, those arrangements continue formally through a range of bilateral agreements and informally through the International Competition Network.

Conclusions

Antitrust policy has undergone incredible change over the twentieth century. As the views about the nature of markets and arrangements among firms held by economists and others have changed, so has antitrust. The early focus was on the possible anticompetitive effects of mergers and other horizontal arrangements among firms. The primary source of market power was the presence of scale economies in production. However, vertical arrangements receive significant critical treatment, and the sources of market power are seen as coming from the demand side as well as the supply side. Further, a wide arrange of contractual practices are now judged as creating substantial efficiencies, albeit with the risk that market power will be used for exclusionary purposes. Finally, significant changes in international competition, resulting from free trade and the communication and information revolution, have reinforced the importance of reshaping antitrust to meet the needs of the twenty-first century. Significant new antitrust challenges lie ahead. Whatever those challenges may be, we can expect that industrial organization economics and antitrust policy will be sufficiently flexible and creative to respond appropriately.

Anxiety and Anxiety Disorders

Klaus Wiedemann, University Hospital Hamburg Eppendorf, Hamburg, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Anxiety is one of the important normally and regularly occurring emotions. Some of the actual public health problems like anxiety disorders are based on the pathology of feelings. Anxiety disorders comprise a heterogeneous group of disorders and each of these disturbances has a different etiology and outcome, and different physiological characteristics. Among the most important influences are actually genetic disposition, environmental impact upon one individual, and acute stressors that result in adaptational changes. Considering a large body of findings, several monoamine neurotransmitters and anxiogenic or anxiolytic-like neuropeptides are involved in the regulation of fear and anxiety.

Anxiety is one of the important normally and regularly occurring emotions, which can be observed throughout all human cultures and in several animal species. Some of the actual most prominent medical and public health problems like anxiety disorders or depression are based on the pathology of feelings (Damasio and Carvalho, 2013). While recent data show that the basic facial expression of emotions is also modulated by culture-specific influences, fundamental emotional expressions such as anxiety or fear originate presumably from the beginning of human ontogeny as biologically hardwired and universal signals (Jack et al., 2013).

Anxiety disorders comprise a heterogeneous group of disorders and each of these disturbances has a different etiology and outcome, and different physiological characteristics. Depending on actual classification rules according to the DSM 5 (2013), panic attacks and panic disorder, phobias, social phobia, and generalized anxiety disorder are summarized in anxiety disorders. In contrast to former classifications, post-traumatic stress disorder and obsessive compulsive disorder are no longer included, despite the fact that anxiety is a relevant dimension of these disorders. Moreover, anxiety has to be differentiated from fear and the so-called stress responses.

Anxiety derives from complex origins and among the most important influences are actually genetic disposition; environmental impact upon one individual, especially early adverse events; and acute stressors that result in adaptational changes. Considering a large body of findings, several monoamine neurotransmitters, for example, gamma-aminobutyric acid (GABA), serotonin, and noradrenalin, are involved in the regulation of fear and anxiety. In addition, an increasing variety of either anxiogenic neuropeptides like corticotropin-releasing factor (CRF), cholecystokinin tetrapeptide (CCK-4), vasopressin, and others, or anxiolytic-like neuropeptides like neuropeptide Y (NPY), neuropeptide S, and atrial natriuretic peptide (ANP) are most important in the modulation of anxiety.

Several neurobiologic findings also stem from investigations in humans by eliciting panic attacks. Panic attacks are unique in the spectrum of psychiatric disorders; since their core psychopathology is temporally limited, they can be provoked under laboratory conditions and can in part be conditioned. Due to the experimental character of these investigations, close comparisons with experiments in animals can be drawn. Hence it has been proposed that panic disorder involves the same pathways that support conditioned fear in animals. However, while induction of panic anxiety has been studied intensively, little is known about the intrinsic mechanisms for the termination of panic and anxiety.

Anxiety or fear is, in addition to happiness, sadness, anger, disgust, and desire, one of the important normally and regularly occurring emotions, which can be observed throughout all human cultures and in several animal species (Ekman, 1982), but the facial expression of such basic emotions is also modulated by culture-specific influences. Anxiety per se is a complicated concept since several difficulties arise in defining this emotion and, in addition, it has to be differentiated from fear and stress (see below). Anxiety occurs, besides in anxiety disorders, also comorbid in several other psychiatric conditions. Moreover, anxiety refers to a variety of other emotional experiences, for example, apprehensiveness, tension, and agitation, which occur also in other emotional states. Anxiety is defined by subjective, behavioral, and physiological characteristics. Anxiety involves the experience of dread and apprehensiveness, and the physiological reactions of anxiety usually include trembling, sweating, elevated heart rate and blood pressure, and increases in muscle tone. Anxiety is defined as pathological when occurring inadequately or with much more pronounced severity and debilitating features. An additional defining criterion in standardized diagnostic manuals is the concomitant occurrence of anxiety and avoidance. Representatives for these diagnostic entities, in which anxiety is the leading symptom, are panic disorder and generalized anxiety disorder. Anxiety is experienced in phobic disorders when the subject is confronted with the feared stimulus, which results in its avoidance. One of the reasons for the declaratory confusion of the term *anxiety* is its psychological similarity to fear and its vegetative similarity to stress. Similar to anxiety, *fear* also includes the experience of dread, and fear seems to be largely included into the concept of anxiety. Moreover, anxiety and fear induce similar bodily reactions, which include the so-called *stress* responses. In general, these can be separated in active responses, known as 'fight or flight' reactions or behavioral inhibition, like freezing. The accompanying stress-related sequelae can again be divided into two large entities: the excitatory fight or flight response postulated by Cannon (1929), and the endocrine stress concept raised by Selye

(1956). Complementarily, the results of several studies indicate that stress involves brain structures, which also mediate the perception of anxiety such as amygdala, hippocampus, and other limbic structures (see below).

Differentiation of Anxiety

Both anxiety and fear are regularly experienced within a range of normal emotional responses of everyday life. Specifically, fear is necessary to achieve personal growth and individual freedom during ontogeny.

Anxiety

Anxiety represents a basic emotional state, which is present in men and can be defined by affective (basic emotional feelings), perceptive (realization of bodily or psychomotor sensations), and cognitive components. Besides these subjective components, behavioral and physiological characteristics can be used to define anxiety phenomenologically. In contrast to experiencing anxiety during everyday life, anxiety as psychopathologic disturbance or anxiety disorder includes specific diagnostic criteria, neurobiological dysfunctions, and a specific genetic background and leads to social and occupational disabilities.

Fear

Fear is the normal reaction to threatening stimuli and is very common in everyday life. When fear is greater than warranted by the situation or starts to occur in inappropriate situations, a specific phobia arises, which belongs to the diagnostic entity of anxiety disorders. One distinction between fear in contrast to anxiety is based upon the presence of commonly defined stimuli, a realistic relation between dangerousness and elicited fear, and the potential to cope with or to adapt to the stimulus. Specific phobias are defined as persistent, irrational, exaggerated, and pathological dreads of a stimulus or situation combined with a compelling desire to avoid this feared challenge.

Stress

Stress is regularly experienced by all organisms, and refers generally to physical or psychological stimuli or alterations that are capable of disrupting the homeostasis of one individual or animal. With regard to psychological aspects of stress, predictability, control, and coping skills are important determinants, which, however, are also threatened during anxiety or fear. Hence, anxiety and fear also represent important psychological stressors with their physiological sequelae being similar to stress reactions. The differentiation between stress and fear is difficult in some situations like free speech, since psychological and biological aspects of stress are linked to each other and are mutually interdependent.

Anxiety Disorders

As defined by means of the diagnostic and statistical manual of mental disorders (*DSM-V* American Psychiatric Association, 2013), anxiety disorders comprise a heterogeneous group, which share *anxiety* as a symptom. However, each of these disturbances has a different etiology and outcome, and different physiological characteristics.

Panic Attacks and Panic Disorder

Panic disorder is characterized by recurrent paroxysmal anxiety, which can even surmount the fear of death during an acute myocardial infarction. These attacks are regularly combined with bodily sensations such as tachycardia, suffocation, shaking, trembling, sweating, abdominal distress, and dizziness. They typically have a sudden onset and are either unpredictable or occur before or during specific situations. The duration of panic attacks is short and ranges between some minutes up to about few hours. If these attacks are affiliated to specific situations, they can lead to avoidance of these specific events and agoraphobia develops, which sustains for longer periods.

Phobias

Phobias are usually differentiated into distinct subtypes: (1) agoraphobia, as frequent sequel of panic disorder, (2) social phobias, and (3) simple phobias. Agoraphobia is the fear of being in situations from which escape is not immediately possible. The symptoms regularly include depersonalization, derealization, dizziness, and cardiac symptoms. Agoraphobia may occur without preceding a panic attack, but remain consolidated between attacks. Social phobias are characterized by the fear that someone may be exposed to a situation where this person is inappropriately scrutinized by others or where this person may behave inadequately. Exposure leads to prominent symptoms of anxiety including bodily alterations, and anticipatory anxiety leads to the avoidance of these situations. Simple phobias are characterized by a persistent fear of a defined object or situation such as fear of spiders or fear of height. The anticipatory anxiety is common and these stimuli are largely avoided, which can impair daily life routines for long periods.

Generalized Anxiety Disorders

This disorder is characterized by excessive worry and by an unspecific, unrealistic, and excessive apprehension about a large variety of future events, which are difficult to control for the person. In addition, symptoms of physiological arousal such as restlessness, autonomic hyperreactivity, sleep disturbances, and muscle tension are characteristics. It has been classified as a chronic disorder lasting longer than 6 months.

Sources of Anxiety in Humans

Anxiety has to be derived from complex origins and interplay of genetic, biological, social, and psychological events and influences. Among the most important factors are the genetic or biological disposition, the developmental and environmental impact upon one individual, and acute stressors and experiences that challenge one person and lead to a variety of adaptational changes.

Genetic and Biological Disposition

Hints for a genetic background of anxiety disorders and indicators for their heritability have been considered as long as for mood disorders, despite the change of diagnostic criteria and labels for different anxiety disorders over the years. Among anxiety disorders, the genetics of panic disorder and generalized anxiety disorder have been most studied. Although panic disorder is the most common anxiety disorder, its underlying etiology is still not well understood. However, several studies have consistently shown that genetic factors explain about half of the variance and that most cases have a complex genetic basis. Existing data suggest that the genetic structures underlying panic disorder seem to be heterogeneous and seem also to differ between cases. The pattern of genes involved might differ in familial versus nonfamilial cases, in early- versus late-onset cases, in different comorbid conditions, but also gender effects and potential subphenotypes have to be considered (Schumacher et al., 2011). From a methodological point of view, family studies, twin studies, linkage and association studies have to be differentiated. Regarding panic disorder, it has been shown that relatives of patients have an increased risk of a similar disturbance. Among relatives a risk of up to 30% is reported, which is significantly different from a lifetime prevalence of about 2% in the general population. Also, twin studies support a heritable component since several studies indicate that the concordance rates for panic disorder are higher in mono- than in dizygotic twins. Linkage studies have been attempted several times, but no single gene loci could be identified. Considering the great complexity of this disorder, it is to be expected that single gene loci are unlikely to be responsible for the diagnostic entity *panic disorder*. However, association studies might lead to the detection of genes responsible for an enhanced vulnerability to anxiety disorders. Interestingly, while single polymorphisms like the transporter for the neurotransmitter serotonin seem to be linked to an altered sensitivity for panic attacks, the respective studies are possibly influenced by selection biases of investigated subjects, which illustrate the complexity of genetic correlations.

Support for a genetic basis of anxiety stems also from preclinical studies. By selective breeding, different lines of rats can be established that differ markedly in their innate anxiety behavior. In genetic knockout, strategies in mice for specific receptors was shown that deficiency of receptors, which are considered to be involved in anxiety and stress reactions, is correlated with a lower innate anxiety behavior. These receptors include particularly the CRF receptor (Steckler and Holsboer, 1999).

Regarding neurogenesis, genetic and epigenetic factors may also regulate the proliferation, survival, and integration of cells into the hippocampus, which is involved in information processing of fearful events. Future studies may therefore elucidate the effect of modulating neurogenesis in animal models of anxiety disorders and the development of proneurogenic compounds may have therapeutic potential (Kheirbek et al., 2012).

Social and Environmental Influences

Although the strong impact of untoward events during childhood is evident, it is worth remembering that simple relationships cannot be constructed. Besides family conflict situations, several factors such as parental support, child-rearing style, and personality traits have been linked to incidence of anxiety disorders in adolescence. Childhood separation anxiety, childhood parental loss, common stressful events, and major life events were predictive for individual susceptibility to develop panic disorder. Interestingly, also the liability to experience a panic attack after inhaled carbon dioxide as panicogenic agent (see below) was increased (Ogliari et al., 2010).

Prospectively ascertained child maltreatment was associated with anxiety disorders, indicating that maltreatment in fact carries an association of anxiety disorders as well as depression and alcohol abuse (Scott et al., 2010). Besides these factors, age also contributes to the expression of anxiety. Anxiety and anxiety disorders have a higher incidence in adolescence that cannot be reduced only to the use of different diagnostic tools, but seems to be related to other reasons.

Life Events

The amygdala and the prefrontal cortex show structural plasticity. Acute and chronic stress cause (see above) an imbalance of neural circuitries involved in anxiety and mood that can increase or decrease expression of those behaviors. In the short term, during increased fearful vigilance and anxiety in a threatening environment, these changes may be adaptive. However, when the danger passes and the behavioral state persists along with changes in neural circuitries, such maladaptation may require intervention in the case of anxiety disorders (McEwen et al., 2012). In context with environmental and developmental influences, traumatic events, which are regularly out of the realm of normal human experience, are of special importance. A traumatic event can lead to increased anxiety after the event, but may have also long-term effects that emerge with future traumas.

Neuronal Basis of Anxiety

Both the increasingly differentiated analysis of anatomical structures, and biochemical and neurophysiological pathways has led to a more detailed concept about the neurobiology of anxiety and especially of panic attacks.

Neuroanatomical Structures

While fear is one of the best investigated emotions in terms of brain mechanisms, a direct comparison of animal models of fear is limited with respect to the spectrum of human anxiety disorders. It has been proposed that panic disorder involves the same pathways that support conditioned fear in animals. These findings support the theory that panic attacks arise from loci in the brain stem that control especially serotonergic and noradrenergic neurotransmission and respiratory control. In addition, also glutamate receptors seem to play a role in fear memory. Further, it was postulated that anticipatory anxiety arises from kindling of limbic areas and phobic avoidance from precortical activation.

Sensory inputs for conditioned stimuli are mediated through the connection of the anterior thalamus to the lateral

and then to the central nucleus of the amygdala. The amygdala is a structure that plays a prominent role in both fear and anxiety: the two components of the amygdala are the central nucleus of the amygdala and the bed nucleus of the stria terminalis. These regions exhibit a high degree of connectivity and play a central role in generating negative emotional responses like fear and anxiety to environmental or conditioned stimuli (Johansen et al., 2011). Interestingly, besides its role in fear processing, the amygdala is considered as structure that detects salient and personally relevant stimuli in cooperation with ventral and dorsal medial prefrontal cortex with both engaged in the processing of socially relevant stimuli (Fossati, 2012).

The central nucleus of the amygdala coordinates physiological and behavioral responses related to anxiety. Efferents of this nucleus have several targets, for example, the parabrachial nucleus producing an increase in respiratory rate, the lateral nucleus of the hypothalamus activating the sympathetic system, the locus coeruleus resulting in an increase in noradrenalin release with its sequelae of increased blood pressure and heart rate and behavioral fear responses, and the nucleus paraventricularis of the hypothalamus causing an increase in corticosteroids via release of neuropeptides like CRF. As outlined by LeDoux (1998), the overlap between effects of brain stem activation by the central nucleus of the amygdala in animals with physiological effects in humans during panic attacks is striking. Besides these connections, mutual interactions between the amygdala and the thalamus, the prefrontal and the somatosensory cortex are obvious. An impairment of the cortical processing could lead to a misinterpretation of visceroafferent cognitions, leading to the activation of the above-mentioned systems. Because of these complex interactions with the autonomic and endocrine regulation, panic attacks apparently result in equivocal physiological and behavioral sequelae (see below) (Gorman et al., 2000).

Transmitter Systems

At least four monoamine transmitter systems, i.e., the noradrenergic, serotonergic, glutamatergic, and GABA system, are involved since several pharmacological compounds provide therapeutic benefit via respective receptors. However, additional neurotransmitter systems have been proposed to underlie anxiety and fear, such as the endocannabinoid system which gives new challenges to investigators.

From clinical experience, the involvement of the GABA system in anxiety and anxiety disorders seems highly important, and for short-term treatment, ligands at the GABA-A receptor like benzodiazepines are extremely helpful due to their rapid onset of anxiolytic action. However, all GABAergic compounds have more or less sedative properties and may induce tolerance, abuse liability, and withdrawal symptoms.

In the past, for many years the balance between GABAergic and glutamatergic systems was pursued in anxiety research. Decreasing the activity of glutamatergic neurotransmission may attenuate excitation in the CNS, thus resulting also in anxiolysis. Moreover, glutamate (especially NMDA receptors) may be involved, besides in fear acquisition, also in fear extinction, which is important in treatment: modulating glutamate neurocircuitries may result directly in therapeutic effects of cognitive therapies.

Further, the monoamine transmitters, serotonin and noradrenalin, and neuropeptides like CRF are important in the regulation of anxiety and fear. Moreover, serotonin neurons in the raphe nuclei have an inhibitory effect on noradrenergic neurons at the locus coeruleus. In addition, these neurons act at the periaquaeductal gray modifying the escape responses and are also thought to inhibit the hypothalamic release of CRF. From a clinical point of view, these findings are supported by therapeutic effects of serotonin reuptake inhibitors. These pharmaceuticals inhibit the uptake of serotonin back into the presynaptic neuron and increase the amount of serotonin in the synapse to bind both to pre- and postsynaptic sites with more than 13 subtypes of serotonin receptors (Kent et al., 1998): a long-term increase of serotonergic transmission by these compounds exerts antipanic and anxiolytic effects.

Another important system is the noradrenergic system (Sullivan et al., 1999). Noradrenalin neurons largely originate in the locus coeruleus and some other nuclei in the medulla and pons. Projection sites include the prefrontal cortex, the amygdala, the hippocampus, the hypothalamus, the thalamus, and the nucleus tractus solitarius. Conversely, the locus coeruleus is innervated by the amygdala. Therefore, the locus coeruleus seems to integrate external sensory and visceral afferents influencing a wide range of neuroanatomical structures related to fear and stress. Clinically it has been proven that, for example, noradrenergic alpha-2 receptor antagonists such as yohimbine can be used to provoke panic attacks acting, whereas clonidine, an alpha-2 adrenergic agonist, exerts anxiolytic-like effects in experimentally induced panic attacks (see below).

All in all it may be summarized that besides serotonin and noradrenalin also glutamatergic and GABAergic transmitters are interacting in complex circuitries, which involve also neuropeptides such as CRF (Arborelius et al., 1999; Koob, 1999). Neurons containing CRF and its receptors have been shown to be distributed throughout the brain, especially the amygdala, the hypothalamus, and the locus coeruleus, and CRF has emerged as a neurotransmitter/modulator that plays a central role not only in stress regulation, but also in anxiety and depression. CRF neurons project from the amygdala to the locus coeruleus. Hence, there are strong hints that CRF could act as a modulator of cognitive and physiological symptoms of anxiety. CRF initiates on one hand a humoral cascade, which enhances via the secretion of corticotropin the release of glucocorticoids, which in turn act at central gluco- and mineralocorticoid receptors. On the other hand, CRF seems directly involved in the modulation of anxiety and depression within the central nervous system. Stress results in increased CRF concentrations in the locus coeruleus and CRF increases the firing rate of noradrenergic neurons. In contrast, noradrenalin also potently stimulates the release of CRF. The involvement of CRF is interesting also with respect to respiratory alterations during panic attacks, which have led to the 'suffocation false alarm theory' (Klein, 1993), since CRF seems to be an important modulator of respiratory centers in the brain stem. Several studies support the contention that antagonists and inhibitors of the synthesis of CRF exert anxiolytic-like effects. Antagonists of CRF receptors have also been examined in clinical trials for their anxiolytic and antidepressant potency.

Since serotonin reuptake inhibitors are involved in the inhibitory regulation of noradrenergic neurons of the locus coeruleus and are thought to reduce the hypothalamic release of CRF, these complex interactions suggest that noradrenergic, serotonergic, and CRF-regulated neurotransmission are linked together with other transmitter circuitries mediating the responses to anxiety, fear, and stress.

Besides CRF, several other neuropeptides are involved in the regulation of anxiety: it was consistently demonstrated that NPY has an inhibitory role in fear acquisition and facilitates fear extinction in animals. In line, also in man abnormally low levels of plasma and cerebrospinal fluid levels of NPY have been found in patients with anxiety disorders (Bowers et al., 2012). Another neuropeptide, i.e., neuropeptide S is of special interest since it exerts anxiolytic effects in animals (Dine et al., 2013), however, effects in humans are still pending.

Models of Anxiety

Anxiety is not merely one of the most important naturally occurring emotions throughout phylogeny and ontogeny, but is also provocapable by different means and can then be readily observed under experimental conditions. Both in humans and in animals, a variety of investigations have been conducted, which allow thorough insights into the pathophysiological conditions and the cognitive and neurobiological processes involved in these specific emotional states.

Animal Models

Animal studies in anxiety can be used both for investigating the physiological and anatomical substrates of anxiety and for studying pharmacological strategies for potential anxiolytic or anxiogenic effects (Westenberg et al., 1996). Basically there are three types of animal behavioral models to detect anxiolytic-like effects. They can be classified in two major groups, i.e., conditioned behavior comprising conflict tests and cognitive-based tests, and unconditioned tests, i.e., ethological behavior. Conditioned behavior detects responses controlled by operant conditioning procedures. Unconditioned behavior is mainly based upon naturally occurring behavior and is called an ethological-based model. A different type is separation models, which mainly investigate the behavior of an offspring during separation from its mother and involves the investigation of developmental disturbances.

Conditioned Emotional Responses

The most important conditioned models comprise conflict models where behavior is suppressed by aversive stimulation. The release of the suppressed behavior without altering the levels of punished responding following pharmacological intervention is estimated as the anxiolytic-like effect. Using these models in rodents, for example, benzodiazepines are consistently effective, whereas for other compounds such as serotonin reuptake inhibitors anxiolytic-like effects are difficult to find. Other important models are the fear-potentiated startle response where the startle response of rats is augmented by fear conditioning. During the conditioning phase, another stimulus is presented signaling the presence of, for example, a shock stimulus. During the startle response, presentation of the stimulus enhances the startle amplitude. Also in this paradigm, benzodiazepines exert anxiolytic effects. In addition to these models, a variety of other conditioned responses and active and passive avoidance reactions can be determined.

Ethological Models

In contrast to the conditioned responses, the ethological models are based upon naturally occurring behavior. The most important and frequently used models are the elevated plus-maze, the open-field, and the dark–light-box models. The elevated plus-maze uses the conflict between exploration and aversion to elevated open places. In this test, anxiety is generated by placing the animal on an elevated open arm, where height and openness rather than light are responsible for anxiogenic effects. The device is shaped as a plus sign with two open arms and two arms enclosed by high walls. The time that rodents spend on the open arms and the number of entries, both, are indicative for anxiolytic-like effects. The open-field test investigates the distance traveled by rodents in a locomotor box within a given time interval. Usually, rodents avoid open areas and try to remain at the edge of the locomotor box. The overall distance traveled and the transitions of the central area of the box are related to the anxiolytic potency by a treatment. The dark–light box uses the number of transitions between a light and a dark, closed compartment as measure of anxiety, since rodents prefer the dark compartment. Peptide-receptor ligands such as CRF (Arborelius et al., 1999) and CCK-4 (Bradwejn and Vasar, 1995) show anxiogenic effects in all three paradigms, whereas other substances such as ANP (Wiedemann et al., 2001) and NPY (Heilig and Widerlöv, 1995) indicate anxiolytic-like effects.

Human Models

The interest in human models of anxiety has been catalyzed to a large extent by findings that panic attacks can be stimulated by a variety of different psychological, physiological, and pharmacological paradigms. Attempts to alter basic anxiety levels and especially those via induction of psychological stress have led to equivocal findings. This might indicate that within the above-mentioned neuroanatomical and physiological systems strong interfering factors exist, which modulate the responses to anxiety and stress.

State and Trait Anxiety

When investigating human anxiety, the distinction between state and trait anxiety is most important and still expanding. State anxiety can be defined as a transitory emotional state consisting of feelings of apprehension, nervousness, and physiological sequelae such as an increased heart rate or respiration (Spielberger, 1979; Endler and Kocovski, 2001). While everyone can experience state anxiety occasionally, there are large differences among individuals in the frequency, duration, and severity. State anxiety can be determined by several rating instruments developed in the past. Trait anxiety represents a fairly stable characteristic related to personality. Experiencing more frequently state anxiety combined with a general view of the world as being threatening and dangerous is used as marker of trait anxiety. The initiation and maintenance of trait anxiety have been related to several factors as outlined above.

Challenge Studies

The profound interest in state anxiety and especially panic attacks stems from a large variety of investigations provoking anxiety and panic attacks experimentally (Nutt and Lawson, 1992). Panic attacks are unique in the spectrum of psychiatric disorders since their core psychopathology of paroxysmal anxiety is temporally limited and can be provoked and investigated under laboratory conditions. Information provided by these studies has led to new cognitive and physiological theories about the basis of panic anxiety and anxiety diseases. Moreover, owing to the experimental character of these investigations, closer comparisons with experiments in animals can be drawn in contrast to other psychiatric animal models. Panic attacks can be elicited by various means, which are listed in Table 1. As indicated, the different paradigms can be differentiated into cognitive, metabotropic, and direct receptor-mediated mechanisms. Especially naturally occurring, cognitive, and metabotropic panic attacks share many features. One of the most amazing findings is that, despite the dramatic anxiety felt, a uniform stress response either of the hypothalamo–pituitary–adrenocortical (HPA, Selye, 1956) or the sympathetic system (Cannon, 1929) is largely missing. These findings led to the hypothesis that in addition to a variety of stimulating agents, strong inhibitors also exist, which physiologically antagonize the altered transmitter and modulator systems involved in panic anxiety. Considering the hypothesis that CRF is one important modulator of anxiety in humans and rodents, it is astonishing that no activation of the HPA system occurs in naturally occurring or metabotropic panic attacks. In contrast, compounds interfering with monoamine and peptide receptors stimulate the HPA activity and the noradrenalin system. Of the latter group, one of the most potent panicogens is CCK-4 (Bradwejn and Vasar, 1995), which seems to exert its effect via CRF. CCK-4 leads dose-dependently to an increase of panic anxiety and a rise of stress hormones. Interestingly, during placebo stimulation following CCK-4 stimulations a psychophysiological conditioning effect could be observed with panic anxiety not accompanied by increases in HPA-axis activity (Hinkelmann et al., 2010). Up to now only a few modulators have been identified, which exert anxiolytic-like effects and, in addition, are able to inhibit the exaggerated HPA system activity. One of these inhibitors might be ANP, which is secreted in the atria of the heart and in various brain regions involved in anxiety. Hence it may be speculated that peptides such as ANP might help to explain the so far unknown mechanisms of terminating panic anxiety (Wiedemann et al., 2001). Despite a tremendously increased knowledge about the induction of anxiety, fear, and stress, the mechanisms of coping and terminating these emotional alterations need further investigations.

Table 1 Experimentally induced panic attacks

Panicogen	*Heart rate stimulation*	*Respiratory stimulation*	*HPA stimulation*	*NE stimulation*
Cognitive stimuli	+	+	−	−
Metabotropic agents				
L-Lactate	+	+	−	−
D-Lactate	+	+	−	−
Bicarbonate	−	+	−	−
CO_2	+/−	+	−	−
Receptor ligands				
Yohimbine	+	−	+	+
Fenfluramine	+	−	+	−
β-Carboline	+	−	+	+
Caffeine	+	+	+	−
CCK-4	+	+	+	(+)
CRF	+	+	+	(+)

HPA, hypothalamo–pituitary–adrenocortical system; NE, noradrenergic system; CCK-4, cholecystokinin tetrapeptide; CRF, corticotropin-releasing factor.

Abstract

Fear conditioning (FC) is a model that has been extremely well characterized over the years, and which has proven invaluable in improving our understanding of the neural basis of anxiety-related disorders. The neural mechanisms that contribute to anxiety per se are less easily isolated into components; yet, owing to significant overlap between the neural circuitry that is engaged in FC and many forms of anxiety-related disorders, researchers in this field have uncovered a role for a number of brain regions in dysregulations of the fear system, including the amygdala, hippocampus, and medial prefrontal cortex.

What Is Anxiety?

Anxiety is a state of prolonged anticipatory worry about a potential threat characterized by an exaggerated fear state, often without the presence of immediate danger, in which there is a hyperexcitability of the fear circuit that includes hypervigilance with increased response (Rosen and Schulkin, 1998). Because pathological anxiety is a chronic and prolonged disorder, it is believed to be a dysregulation within the fear circuit leading to neural and behavioral sensitization of this network. Anxiety is believed to develop from initially adaptive fear responses to environmental threats. Such fear responses may include behavioral manifestations such as freezing, startle, defensive withdrawal, or escape, as well as physiological responses, including changes in heart rate, and blood pressure. However, unlike an acute response to an immediate threat, anxiety develops into a cognitively modulated chronic fear state, even without the presence of a threat, which can then cause generalization over time and situations.

One of the biggest challenges to the study of anxiety disorders is that they consist of a cognitively subjective sense of worry or fear that often occurs in the absence of true danger. It is difficult for anxiety to be measured explicitly, especially in nonhuman animal models, because we cannot easily determine, if an animal is feeling chronically anxious. However, some measures of anxiety-like behaviors in animal models have been developed based on innate threats that animals face. In such models, rather than presenting a direct threat, we can manipulate situations in which danger may be possible and measure responses to the situation. Still, anxiety-related responses remain difficult to assess. Rather, most researchers in the field rely on fear-learning paradigms (such as fear conditioning (FC)) to make inferences about anxiety and anxiety-related disorders.

What Is FC?

Pavlovian FC is a form of associative learning in which an innately neutral stimulus, conditioned stimulus (CS, e.g., a tone or context), is paired with an emotionally eliciting stimulus, an unconditioned stimulus (US, e.g., a shock) causing an unconditioned response (e.g., freezing) to the US, which then becomes a conditioned response (CR, e.g., freezing). This process creates an association between the CS and US from which the presentation of the CS alone will begin to elicit the CR without the US. FC is one of the most studied forms of learning because it occurs quickly, a single CS–US pairing is sufficient to create a long lasting and stable memory. In addition, the brain mechanisms involved in FC have been extensively studied and mapped over the last few decades, and overlap greatly with those engaged in anxiety-related disorders.

Why Is FC Important and How Can It Be Used to Better Understand Anxiety?

The neurological roots of anxiety lie within the same innate responses found in FC, as such FC provides a more direct way to better understand some of the mechanisms that underlie both fear and anxiety. One of the biggest benefits to the study of FC is that the different stages of conditioning can be isolated and targeted to better understand the specific mechanisms that regulate learning and associated brain responses. The most common way fear is examined is through freezing (that is, cessation of movement in the presence of a threatening stimulus), which can be reliably measured across species.

Brain Regions Implicated in Different Phases of FC

Acquisition

Acquisition is the initial phase of FC in which there is convergence of information about the CS and the US, which leads to associative learning and plasticity.

Two of the most common ways in which FC is studied is through the use of either a CS to a discrete cue (such as a tone) or a context. While both conditioning paradigms work in similar fashions, the sensory information from each stimulus is integrated in different ways. In a condition in which a tone is used as the CS, inputs from the medial geniculate nucleus of the thalamus and auditory association cortex (TE3) converge in the lateral amygdala (LA) where the auditory and somatosensory inputs are then processed (Doron and Ledoux, 1999). Alternatively, in a conditioning paradigm in which a context is used as the CS, projections from the hippocampus to the

amygdala have been identified to be important for integrating the two stimuli (Phillips and LeDoux, 1992; Maren et al., 1998). Additional work has also found that the hippocampus plays a role in trace FC, which determines how time between the introduction of the US and CS effects conditioning (Phillips and LeDoux, 1992; McEchron et al., 1998).

However, through more refined techniques, which allow functional inactivation of subregions through GABA agonists, for brief periods of time, region specificity has been further examined. Wilensky et al. (1999) were able to show that functional inactivation of both the LA and basolateral amygdala (BLA) subnuclei could block fear acquisition. Yet, when those regions were blocked after initial acquisition there was no effect on consolidation of the memory, distinguishing these regions specific roll in the acquisition of a fear memory.

Additionally work has been done to confirm findings from nonhuman animal studies through human imaging, identifying that both the amygdala and hippocampus become active during acquisition (LaBar et al., 1998; Knight et al., 2004). Additional support of fear acquisition in humans has come from trace conditioning, which requires a larger cognitive load. Imaging studies have shown that again both the amygdala and hippocampus become activated during acquisition (Büchel et al., 1999).

In one study, Phelps and colleagues instructed participants that one stimulus would predict shock whereas a second stimulus would not and found that in fact the left amygdala of participants became activated when the stimulus they were told would predict shock was presented (Phelps et al., 2001). This result is consistent with research done with participants who have had left temporal lobotomy who also show deficits in their ability to acquire fear from instruction rather than experience (Funayama et al., 2001). Work by Anderson and Phelps (2002) found that in fact patients that have had lesions to their amygdala can still experience emotion and both positive and negative affective states. This comes with the fact that patients cannot, however, learn new fear associations (LaBar et al., 1995; Weike et al., 2005).

Consolidation

Another important aspect of the formation of a fear memory is that an association between the two stimuli is created and a memory is retained. If during conditioning, the aversive US is introduced with the neutral CS and in that instant a response to the US is made, yet an association is not acquired and retained into a memory no conditioning may have occurred.

Over the last decade, lot of work has been done to determine what regions are specifically involved in the consolidation process because unlike other aspects of conditioning it must be targeted in a time-sensitive way, after initial acquisition but not effect expression. Through methodologies previously discussed functional inactivation immediately posttraining are used to access what brain regions are important for consolidation of fear-related memories.

As expected contextual and cued FC show differences in region specificity of consolidation. Using a neurotoxin to functionally inactivate different regions, the BLA, Entorhinal Cortex (EC), and Perirhinal Cortex (PC) resulted in deficits in consolidation of cued FC, while inactivating the thalamus did not have an effect (Sacchetti et al., 1999). Conversely, similarities of functional inactivation of the BLA, EC, and PC were also seen in contextual FC, however, in addition inactivation of the hippocampus caused deficits in consolidation.

Expression

The BLA was one of the first regions assessed for its effects on expression of fear, as it is the region in which information from the CS and US in both cued and contextual fear. Research has supported, with lesions to the BLA 1 or 15 days after training can eliminate freezing expression to both a context and cued fear (Cousens and Otto, 1998; Angladа-Figueroa and Quirk, 2005). Similarly, functional inactivation of the BLA resulted in attenuated fear expression if induced 24 h after training but before test (Helmstetter and Bellgowan, 1994). However, the action of the BLA is still under debate because, while lesioning or inactivating the BLA shows effects on expression, it is not known if the BLA has a direct behavioral contribution to expression, because it has both direct and indirect connections to the Central Nucleus of the Amygdala (CeA) (LeDoux, 2000). Whereas the CeA is known to have direct connections to the startle circuit, including the periaqueductal gray, lateral hypothalamus, and paraventricular nucleus of the hypothalamus, which modulate the physiological and behavioral responses to FC (LeDoux, 2000; Maren, 2005; Kim and Jung, 2006).

Differently from other aspects of FC, a few new regions of interest become important for fear expression including, the Ventral Tagmental Area (VTA), and Nucleus Accumbens (NAcc) (see review, Pezze and Feldon, 2004). These regions contribute to the motor output of fear expression. In FC, the NAcc receives input both from the VTA as well as the BLA, from which it then can relay information to other regions of the basal ganglia to evoke motor output.

Additionally, within recent years a greater interest has begun to examine the role of the Prefrontal Cortex (PFC) plays in FC. Research in fact has found that the medial prefrontal cortex (mPFC) may be required to express proper fear responses in FC (Lee and Choi, 2012). Similarly to the specialties of the amygdala subregions, the PFC subregions also show distinctions in their roles. While the infralimbic subregion of the mPFC works by inhibiting amygdala output, the prelimbic mPFC works to modulate expression through exciting amygdala output (Vidal-Gonzalez et al., 2006).

Extinction

One of the most important reasons to study FC is not just to better understand fear, but also how to eliminate fear or the aspects that contribute to fear and anxiety-related disorders. Extinction is the most commonly practiced technique to attempt to alter the effects of the original CS–US relationship. Through presentations of the CS over multiple trials without the aversive US, extinction training leads to decreases in the CR to the presentation of the CS. Data support that similar to initial fear learning, the amygdala acts to acquire and store extinction memories, while the hippocampus processes contextual information, and the infralimbic region of the

mPFC engages in consolidation and the retrieval of extinction memory (Myers and Davis, 2006; Quirk and Mueller, 2008).

Supporting the translational relationship between animal work and humans, the amygdala as well as the hippocampus are critical to extinction in humans (Knight et al., 2004). In addition, the mPFC is necessary in extinction, possibly through inhibitory signaling, this corresponding to work that has found that the orbitofrontal and ventromedial prefrontal cortices become activated during extinction learning and recall (Phelps et al., 2004; Gottfried and Dolan, 2004; Milad et al., 2007; Kalisch et al., 2006).

However, one concern with fear extinction is that it is a form of new learning, and has all the components of the original FC, so rather than changing the old memory extinction is creating a new memory that competes with the old association, from which you hope that when retrieving a memory upon presentation of the CS, one retrieves the safety memory (or extinguished memory) (Bouton, 2002). However, when the CS is presented after extinction spontaneous recovery can occur, in which with the passage of time rather than the safety memory being expressed the fear response is elicited (Rescorla, 2004). Alternatively, if the US is presented but not signaled with the original CS reinstatement of the original association can occur, causing an expression of fear in the presence of the CS without reconditioning (Delamater, 1997). Finally, renewal can occur, in which the fear response is elicited in the context it was learned but not in the context in which it was extinguished, this is also an issue with generalizability of extinction (Effting and Kindt, 2007).

Reconsolidation

When new memories are formed consolidation must occur over time, to create long-term memories (LTMs). Similarly, when memories are retrieved from LTM they become progressively unstable (Hong et al., 2013; Kim et al., 2010), at which point they must then be reconsolidated into LTMs once again. While, within a window of accessing a previously established memory and it becoming reconsolidated the memory is considered unstable and in a labile state, and by such can be altered or strengthened before being reconsolidated into LTMs again. Adaptively, this makes sense because if you encounter the same situations over time you want to keep updating existing information rather than creating a new memory or association every time similar circumstances arise. This also facilitates an alternative to extinction for the reduction of fear responses to a stimuli and a way to update rather the overwrite an already established memory. Research has found that this both occurs within the hippocampus for contextual FC as well as the amygdala for both context and cued FC, both of which occur in a temporally graded manner (Debiec et al., 2002; Parsons et al., 2006).

Neural Mechanisms and Modulators Implicated in FC

With the development of better and more precise techniques to assess region specificity for different behaviors and/or disorders, we have begun to identify some of the neural modulators and mechanisms that are critical in FC (for a recent comprehensive review see Johansen et al., 2011). One neural modulator, however, has been found to play an integral role in learning, FC, and as we later discuss anxiety, the ionotropic glutamatergic receptor *N*-methyl-D-aspartate (NMDA) (Tsien, 2000). In FC, NMDA receptors in the LAs have been found to play multiple roles, including roles in both contextual and cued fear, acquisition, expression, and extinction (Rodrigues et al., 2001; Maren et al., 1996; Zimmerman and Maren, 2010). In the expression of fear responses, NMDA receptors within the NAcc modulate Dopamine (D) within the VTA under stressful conditions, potentially working in a feedback manor (Doherty and Gratton, 1997). Consolidation of extinction can be impaired through blockade of NMDA receptors in the mPFC or reduction of Brain-derived Neurotropic Factor signaling within the amygdala (Burgos-Robles et al., 2007; Chhatwal et al., 2006).

Additionally the neural process of plasticity and long-term potentiation (LTP) function though NMDA modulation between synapses (Samson and Paré, 2005), through L-type voltage-gated calcium channels on NMDA signaling between the thalamus to the amygdala (Weisskopf et al., 1999). The process of neural plasticity and LTP is believed to be important in FC, in that after an association has occurred the strength of that association follows the Hebbian theory of plasticity, in which, when a presynaptic neuron fires causing a response in a postsynaptic neuron it increase the strength or relationship between the two neurons (Hebb, 1949). In associative learning, it is interpreted that if you have a strong presynaptic input from one neuron, and another presynaptic neuron also acts on the same postsynaptic neuron it will increase the relationship between the strong acting neuron as well as the weaker acting neuron, through an increased nonspecific association. This is how an association between a CS and US is strengthened to elicit the same response, even though prior to experience with the CS and US, the CS did not elicit the CR.

The effects of plasticity have been shown through changes in synaptic transmission and strength between pre- and postsynaptic neurons in both contextual and cue FC between the hippocampus to amygdala, and thalamus to the amygdala, respectively (Maren and Fanselow, 1995; McKernan and Shinnick-Gallagher, 1997; Quirk et al., 1997). For example, previously unresponsive cells in cued conditioning can become tone-responsive cells with training (Quirk et al., 1995). Additionally, other mechanisms have been found to be important in plasticity, norepinephrine (NE) works through trafficking alpha-amino-3-hydroxy-5-methyl-4-isoxazoleproprionic acid (AMPA)-type glutamate receptors AMPA to the synapse, which in turn decreases the threshold necessary for LTP to occur (Tully and Bolshakov, 2010; Hu et al., 2007).

Other phases of FC show differences in the neural mechanisms that contribute to their processes. In reconsolidation, the blockade of downstream mitogen-activated protein kinase cascade within the amygdala has an effect on protein modulation within a cell and can be targeted to inhibit reconsolidation (Duvarci et al., 2005). This function has been found to be important because of its use in fear memory updating, similar to initial consolidation when protein synthesis is inhibited within the consolidation window it can block the memory and specifically in reconsolidation block spontaneous recovery, reinstatement, and renewal (Schafe and LeDoux,

2000; Duvarci and Nader, 2004). However, non-pharmacological interventions have been shown to modulate this neural process. One such technique employs both reconsolidation, by introduction of a single retrieval session to reactive initial memory trace, then an extinction trial is used to modulate the initial fear memory within the critical reconsolidation window, such that the memory is now updated to the CS no longer predicts the US (Monfils et al., 2009).

Neural and Behavioral Mechanisms of Anxiety

While FC is one of the most commonly and well-respected ways of studying fear, other behavior paradigms can be employed to study fear and anxiety. Similarly, to FC anxiety can be studied in animal models to better understand innate behavioral and emotion responses under a specific circumstance. One challenge to the study of anxiety-like tasks in animal models is that they are not necessarily a direct comparison to human anxiety in the same way that fear responses are between nonhuman animals and humans. As previously mentioned, pathological anxiety in humans is a chronic and relapsing disorder; however, the current models of anxiety-like behavior in animals measure acute interactions of animals when introduced to a biologically significant challenge. Some work, however, has tried to use chronic stress models to emulate the chronic nature of anxiety; however, this will not be discussed here. Anxiety-like measures do offer some benefits and similarities to human anxiety, because behavior can both be assessed under conditioned or unconditioned terms, so one can measure learning and associations as well as an ecologically influenced choice of response.

One paradigm used to assess fear and anxiety through conditioning is fear-potentiated startle (FPS), in which a loud noise (aversive stimulus) is presented with a CS previously paired with a US and differences in startle response to the loud noise alone verse the loud noise plus CS is assessed. Similarly, to basic FC lesions to the amygdala block FPS (Kim and Davis, 1993). More specifically, the blockage of NMDA receptors within the amygdala block both acquisition and extinction of FPS, with some support that it can also block expression (Campeau et al., 1992; Falls et al., 1992; Fendt, 2001). Consistent with FC, FPS employs the mescorticolimbic pathway in startle responses, and both functional inactivation as well as dopaminergic blockade within this pathway can attenuate expression (Munro and Kokkinidis, 1997; de Oliveira et al., 2009).

One of the most commonly used tests to assess anxiety-like behavior is an unconditioned task, the Elevated-Plus Maze (EPM). This task examines the challenge of an animal to explore novel environments (innately desirable), at the cost of two of the four arms, being open to the outside environment, creating vulnerability and potential danger (Montgomery, 1955). This test has been integral in development of new pharmacological tools to understand anxiety disorders. The most well-documented include benzodiazepines, which work through enhancing GABAnergic transmission, as well as buspirone, which functions as a partial agonist of serotonin and dopamine. Both types of pharmacological manipulations increase open arm entries and as such are believed to reduce anxiety (Cole and Rodgers, 1993, 1994, 1995). Additionally, the EPM task and other anxiety-like measures have provided availability to understand what factors influence increases in anxiety, such as social defeat or isolation (Heinrichs et al., 1992; Maisonnette et al., 1993), restraint (Martijena et al., 1997), or previous shock exposure (Korte et al., 1999).

Anxiety-like tasks have been essential in finding neural mechanisms through which anxiety is modulated. Corticotrophin-releasing factor (CRF) and hyperactivity in the hypothalamic-pituitary-adrenal (HPA) axis have been found to influence fear and anxiety (Lelas et al., 2004). Additionally, the glutamatergic system has been found to be involved not only in FC but anxiety, with the use of antagonists for the mGluR5 subunit of glutamate receptor reducing anxiety-like behavior on anxiety tasks (Brodkin et al., 2002).

Neuronal activation upon exposure to the EPM has identified regions involved in anxiety that also overlap with FC, including; the amygdala, hippocampus, thalamus, and periaqueductal gray matter, as well as other regions within the brain stem (Silveira et al., 1993). One area that has been shown to be differentially activated in anxiety from FC is the noradrenergic Locus Coeruleus and may provide a good target for anxiety treatment (Chrousos and Gold, 1992).

One research tool that is being developed is animal models that encompass similar pathologies of human anxiety. Steps for the future of developing these pathological models of anxiety in animals come for the fact that anxiety disorders run in families, supporting the idea that there may be a genetic influence on the development of anxiety disorders (Merikangas and Pine, 2002). Current data from twin studies provide evidence that anxiety disorders are heritable (Hettema et al., 2001; Skre et al., 2000; Goldberg et al., 1990). Studies of children whose parents have been diagnosed with an anxiety disorder have found that the children exhibit greater startle responses, indicative of an increased anxiety response (Grillon et al., 1998). However, it has also been found that genetic disposition is not the only factor that plays into the development of anxiety disorder that environmental influences play an important role as well (Hettema et al., 2005).

Post-traumatic stress disorder (PTSD) is one of the most common anxiety disorders effecting approximately 7% of people over a lifetime (Kessler et al., 2005). Closely following similar acquisition of Pavlovian FC, PTSD is believed to develop when a person is exposed to a traumatic event, which then leads to a chronic anxiety state, as well as potentially direct or generalized associations between stimuli and the trauma. Patients with PTSD have been found to have increased startle and aversive CRs as well as resistance to extinction (Grillon and Morgan III, 1999; Jovanovic et al., 2010). These behavioral metrics may be due to increases in heart rate and skin conductance at baseline, which may be indicative of an overactive sympathetic nervous system and HPA axis. These findings also follow patterns of anxiety in animal models.

Also contributing to the understanding of PTSD in human imaging studies that expand on the fact that in both human and animal models of FC show an importance of the PFC for extinction in healthy individuals. Consistent with those findings, patients with PTSD show deficits in activation in both the mPFC and the anterior cingulate while engaged in emotional tasks (Shin et al., 2005, 2001). Additional alterations include

increased amygdala activation during acquisition, as well as exaggerated responses in the putamen, insula, caudate, and amygdala to the US (Bremner et al., 2005; Linnman et al., 2011; Shin et al., 2005).

Consistent with PTSD patients, patients with panic disorder have also been found to show increased startle responses in a FPS test (Grillon et al., 1994). Patients with generalized anxiety disorder also show analogous deficits in anterior cingulate activation and connectivity with the amygdala within an emotional processing task (Etkin et al., 2010).

Conclusion

In conclusion, there are many overlapping neural mechanisms and brain regions specifically involved in FC and anxiety. This is seen through both assessing the isolated phases of FC, as well as through multiple anxiety-like tasks in nonhuman animals, while demonstrating support for the neural correlates in human imaging and case studies. These include the amygdala, hippocampus, thalamus, periaqueductal gray, and mPFC, which have been shown to be important in both FC and anxiety, see Table 1. Additionally, neural mechanisms in the mesocorticolimbic pathway modulating dopamine are important for fear expression and FPS responses in nonhuman animals. It is clear that studying basic fear models has dramatically improved our understanding of anxiety-related disorders over the years. As we proceed forward, many researchers in the field believe that continued interactions between basic researchers and clinicians will facilitate the development of better tools to help individuals with anxiety-related disorders.

Table 1 Brain regions discussed to be involved in fear conditioning, all bolded regions are those that overlap regions discussed to be involved in anxiety

Phases of fear conditioning	*Brain regions*
Acquisition	**Amygdala**
	Auditory association cortex
	Hippocampus
	Thalamus
Consolidation	Amygdala
	Hippocampus
	Medial temporal lobe
Expression	**Amygdala**
	Hypothalamus
	Periaqueductal gray
	Medial prefrontal cortex
	Nucleus accumbens
	Ventral tagmental area
Extinction	**Amygdala**
	Hippocampus
	Medial prefrontal cortex
Reconsolidation	Amygdala
	Hippocampus

Aphasia

Abstract

Aphasia is a disturbance of the use of language due to disease of the brain. Early approaches to describing aphasia emphasized patients' abilities to speak, understand spoken language, and read and write, and paid little attention to the elements of language that were affected in these tasks or how they were affected. These theories have provided a basis for classifying aphasias and for relating some aspects of language to the brain that is still in clinical use. Modern approaches to aphasia try to delve deeper into the nature of aphasic impairments, by saying what parts of language are affected (e.g., problems with comprehension of sentences could be due to problems affecting word recognition, not knowing what words mean, or not being able to relate words to one another in a sentence), and how they are affected. This article presents an overview of aphasia, beginning with the traditional clinical descriptions and ending with more modern approaches.

Aphasias are disturbances of language following diseases of the brain. Clinical approaches to describing aphasias evolved from nineteenth-century descriptions that emphasized the language task that was affected – speaking, understanding spoken language, reading, and/or writing – and a limited description of the linguistic impairments in patients, such as whether a disturbance of speech affected grammatical forms or content words. This approach was related to a model of where the processing of speaking, understanding spoken language, reading, and writing simple words was located in the brain, and has given rise to a set of aphasic syndromes that are widely recognized by clinicians today. Modern descriptions of aphasic patients have taken major steps toward capturing the details of the linguistic impairments in patients. This research has led to better understanding of how language processing is organized and how it breaks down. However, the goal of understanding the relation between language processing operations and brain structures remains to be achieved.

Definition

The term 'aphasia' refers to disorders of language following diseases of the brain. As is discussed in other articles in this encyclopedia, language can be conceived of as a distinctly human symbol system that relates a number of different types of forms (words, words formed from other words, sentences, discourse, etc.) to various aspects of meaning (objects, properties of objects, actions, events, causes of events, temporal order of events, etc.). The forms of language and their associated meanings are activated in the processes of speaking, understanding speech, reading, and writing. The processes whereby these forms are activated are largely unconscious, obligatory once initiated, fast, and usually quite accurate. Disturbances of the forms of the language code and their connections to their associated meanings, and of the processes that activate these representations in these ordinary tasks of language use, constitute aphasic disturbances. By convention, the term 'aphasia' does not refer to disturbances that affect the functions to which language processing is put. Lying (even transparent, ineffectual lying) is not considered a form of aphasia, nor is the garrulousness of old age or the incoherence of schizophrenia.

Language consists of a complicated system of representations, and its processing is equally complicated, as described in other articles in this encyclopedia. Just the representation of the minimal linguistically relevant elements of sound – phonemes – and the processing involved in recognizing and producing these units constitute a highly complex domain of functioning. When all the levels of language and their interactions are considered, language processing is seen to be enormously complex. Aphasic disturbances would therefore be expected to be equally complex. Researchers are slowly describing the very considerable range of these disorders.

History of the Field: The Classic Aphasic Syndromes, and Alternative Views

The first modern scientific descriptions of aphasia were quite modest with respect to the descriptions of language processing that they contained. These descriptions were made by neurologists in the second half of the nineteenth century. Though modest with respect to the sophistication of the descriptions of language, these studies laid important foundations for the scope of work on aphasia and for the neural basis for language processing, which has always been a closely associated topic. The first of these late nineteenth-century descriptions was that by Broca (1861), who described a patient, Leborgne, with a severe speech output disturbance. Leborgne's speech was limited to the monosyllable 'tan.' Broca described Leborgne's ability to understand spoken language and to express himself through gestures and facial expressions, as well as his understanding of nonverbal communication, as being normal. Broca claimed that Leborgne had lost 'the faculty of articulate speech.' Leborgne's brain contained a lesion whose center was in the posterior portion of the inferior frontal convolution of the left hemisphere, an area of advanced cortex just adjacent to the motor cortex. Broca related the most severe part of the lesion to the expressive language impairment. This area became known as 'Broca's area.' Broca argued that it was the neural site of the mechanism involved in speech production.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.54001-X

In a second very influential paper, Wernicke (1874) described a patient with a speech disturbance that was very different from that seen in Leborgne. Wernicke's patient was fluent; however, her speech contained words with sound errors, other errors of word forms, and words that were semantically inappropriate. Also unlike Leborgne, Wernicke's patient did not understand spoken language. Wernicke related the two impairments – the one of speech production and the one of comprehension – by arguing that the patient had sustained damage to 'the storehouse of auditory word forms.' The lesion in Wernicke's case was unknown, but a lesion in a similar case was the area of the brain next to the primary auditory receptive area, which came to be known as Wernicke's area.

These pioneering descriptions of aphasic patients set the tone for much subsequent work. First, they focused the field on impairments of the usual uses of language – speech, later on reading and writing. This seems like an obvious area for aphasiology to be concerned with, but not all researchers of the period agreed with this focus. In another famous paper, the influential British neurologist John Hughlings Jackson (1878) described a patient, a carpenter, who was mute but mustered up the capacity to say 'Master's' in response to his son's question about where his tools were. Jackson's poignant comments convey his emphasis on the conditions that provoke speech, rather than on the form of the speech itself:

> The father had left work; would never return to it; was away from home; his son was on a visit, and the question was directly put to the patient. Anyone who saw the abject poverty the poor man's family lived in would admit that these tools were of immense value to them. Hence we have to consider as regards this and other occasional utterances the strength of the accompanying emotional state.
>
> Jackson, 1878, p. 181

Jackson sought a description of language use as a function of motivational and intellectual states, and tried to describe aphasic disturbances of language in relationship to the factors that drive language production and make for depth of comprehension. Broca, Wernicke, and the researchers who followed focused aphasiology on patients' everyday language use under what were thought to be normal emotional and motivational circumstances.

These and related subsequent papers tended to describe language impairments in terms of the entirety of language-related tasks – speaking, comprehending, etc. – with only passing regard for the details of the language forms that were impaired within a task. A patient's deficit was typically described in terms of whether such an entire function was normal or not, and whether one such function was more impaired than another was. Here, for instance, is the description of Broca's aphasia by two twentieth-century neurologists whose work follows in this tradition:

> The language output of Broca's aphasia can be described as non-fluent … Comprehension of spoken language is much better than speech but varies, being completely normal in some cases and moderately disturbed in others.
>
> Benson and Geschwind, 1971, p. 7

The one level of language that descriptions did tend to concentrate on was the level of words. For instance, in the same passage, Benson and Geschwind point out that patients with Broca's aphasia often omit function words (e.g., determiners such as 'the') and word endings, but produce at least some nouns. Altogether, the clinical approach to aphasia, derived most directly from early work, emphasized the usual tasks of language use and just began to describe impairments in linguistic and psycholinguistic terms. This approach to aphasia led to the recognition of 10 classical aphasic 'syndromes.' These are listed, along with their proposed neural bases, in **Table 1**.

Psycholinguistic Approaches to Aphasia

As noted in the previous section, the classical aphasic syndromes do not give a complete account of the range and specificity of aphasic impairments. More recent descriptions of aphasia add many details to the linguistic and psycholinguistic descriptions of these disorders. It is impossible to review all these impairments in the space of a short article, but a few examples will illustrate these results. For instance, at the first step of speech processing – converting the sound waveform into linguistically relevant units of sound – researchers have described specific disturbances affecting the ability to recognize subsets of phonemes such as vowels, consonants, stop consonants, fricatives, nasals, etc. (Saffran et al., 1976). In the area of word production, patients have been described with selective impairments of the ability to produce the words for items in particular semantic categories, such as fruits and vegetables, but sparing animals and man-made tools (Hart et al., 1985); selective impairments affecting the ability to produce nouns and verbs (Damasio and Tranel, 1993); and other highly restricted deficits. In the area of reading, patients have been found to have impairments of the ability to sound out novel written stimuli using letter–sound correspondences but retained abilities to read familiar words, and vice versa (Marshall et al., 1980; Patterson et al., 1985).

Linguistic theory provides a basis for exploring the nature of aphasic disorders by providing evidence for different types of linguistic representations. Models of the psychological processes involved in activating linguistic representations suggest other possible loci of impairment. Many researchers have worked backward from clinically observed phenomena, developing or modifying theories of language structure and processing on the basis of the disorders seen in aphasic patients. For instance, the finding of patients with disorders of the ability to sound out novel written stimuli but retained abilities to read familiar words and vice versa has led to a model of reading in which there are two ways of pronouncing a written word – sounding it out and recognizing it as a whole. This model is controversial, and some of the strongest evidence for it remains the performance of aphasic patients (Coltheart et al., 2001). Characterizing aphasic disorders is an interactive, interdisciplinary, bootstrapping process that is presently in active evolution.

The psycholinguistic approach to aphasia is based upon a model of language structure and processing. Experts disagree about these models. Some of the greatest disagreements center on the issue of the extent to which linguistic representations are

Table 1 Classical aphasic syndromes

Syndrome	*Clinical manifestations*	*Postulated deficit*	*Classical lesion location*
Broca's aphasia	Major disturbance in speech production with sparse, halting speech, often misarticulated, frequently missing function words, and bound morphemes	Disturbances in the speech planning and production mechanisms	Posterior aspects of the third frontal convolution (Broca's area)
Wernicke's aphasia	Major disturbance in auditory comprehension; fluent speech with disturbances of the sounds and structures of words (phonemic, morphological, and semantic paraphasias)	Disturbances of the permanent representations of the sound structures of words	Posterior half of the first temporal gyrus and possibly adjacent cortex (Wernicke's area)
Pure motor speech disorder	Disturbance of articulation, apraxia of speech, dysarthria, anarthria, aphemia	Disturbance of articulatory mechanisms	Outflow tracts from motor cortex
Pure word deafness	Disturbance of spoken word comprehension	Failure to access spoken words	Input tracts from auditory system to Wernicke's area
Transcortical motor aphasia	Disturbance of spontaneous speech similar to Broca's aphasia with relatively preserved repetition	Disconnection between conceptual representations of words and sentences and the motor speech production system	White matter tracts deep to Broca's area connecting it to parietal lobe
Transcortical sensory aphasia	Disturbance in single word comprehension with relatively intact repetition	Disturbance in activation of word meanings despite normal recognition of auditorily presented words	White matter tracts connecting parietal lobe to temporal lobe or portions of inferior parietal lobe
Conduction aphasia	Disturbance of repetition and spontaneous speech (phonemic paraphasias)	Disconnection between the sound patterns of words and the speech production mechanism	Lesion in the arcuate fasciculus and/or corticocortical connections between Wernicke's and Broca's areas
Anomic aphasia	Disturbance in the production of single words, most marked for common nouns with variable comprehension problems	Disturbances of concepts and/or the sound patterns of words	Inferior parietal lobe or connections between parietal lobe and temporal lobe; can follow many lesions
Global aphasia	Major disturbance in all language functions	Disruption of all language processing components	Large portion of the perisylvian association cortex
Isolation of the language zone	Disturbance of both spontaneous speech (similar to Broca's aphasia) and comprehension, with some preservation of repetition	Disconnection between concepts and both representations of word sounds and the speech production mechanism	Cortex just outside the perisylvian association cortex

highly abstract structures that are produced and computed in comprehension tasks by rules (Chomsky, 1995), as opposed to far less abstract representations that are processed largely by highly developed pattern associations (Rumelhart and McClelland, 1986). If language is seen in the former perspective, many aphasic impairments are considered to be the result of damage to specific representations and/or processing operations. If language is seen in the latter perspective, aphasic disturbances are largely conceptualized as resulting from reductions in the power of the associative system, due to loss of units, increases in noise, etc. Empirical study suggests that both specific impairments and loss of processing power are sources of aphasic disturbances. This can be illustrated in one area – disorders affecting syntactic processing in sentence comprehension.

Disorders of syntactically based comprehension affect the ability to extract the relationships between the meanings of words in a sentence that are determined by the syntactic structure of a sentence. For instance, in the sentence 'The dog that scratched the cat killed the mouse,' there is a sequence of words – the cat killed the mouse – which, in isolation, would mean that the cat killed the mouse. However, this is not what the sentence means, because of its syntactic structure. 'The cat' is the object of the verb 'scratched'; 'the dog' is the subject of the verb 'killed' and is the agent of that verb. Caplan and his colleagues have explored the nature of these disturbances (Caplan et al., 1985, 1996). They found that, in many hundred of aphasic patients, mean group performance deteriorated on sentences that were more syntactically complex and that more impaired groups of patients increasingly performed more poorly on sentences that were harder for the group overall. These patterns suggest that the availability of a processing resource that is used in syntactic comprehension is reduced to varying degrees in different patients. A second finding in their studies has been that individual patients can have selective impairments of syntactic comprehension, just as is the case in the other areas of language processing previously mentioned. Published cases have had difficulty constructing hierarchical syntactic structures, disturbances affecting reflexives or pronouns but not both, and other more subtle impairments of syntactic processing (Caplan and Hildebrandt, 1988).

Overall, these studies suggest that a patient's aphasic impairment can be described in terms of a reduction in the processing resources needed for this function and disruption to specific operations. An unresolved question is whether the entire pattern of performance seen in these disorders can be attributed to just one of these types of impairments, as the two types of models previously outlined maintain. This may be possible, but the challenges in explaining all these aspects of these (and other) aphasic disorders within a model that

either does not incorporate the idea of a processing resource limitation or does not recognize specific operations are considerable.

Functional Consequences of Aphasic Impairments

The focus of this article has thus far been on aphasic disturbances as impairments of the largely unconscious processes that activate the elements of language in the usual tasks of language use. The functional consequences of these disorders deserve a brief comment. Functional communication involving the language code occurs when people use language to accomplish specific goals – to inform others, to ask for information, to get things done, etc. There is no simple, one-to-one relationship between impairments of elements of the language code or of psycholinguistic processors, on the one hand, and between abnormalities in performing language-related tasks and accomplishing the goals of language use, on the other. Patients adapt to their language impairments in many ways, and some of these adaptations are remarkably effective at maintaining at least some aspects of functional communication. Conversely, patients with intact language processing mechanisms may fail to communicate effectively. Nevertheless, most patients who have disturbances of elements of the language code or psycholinguistic processors experience limitations in their functional communicative abilities. In general, as the intentions and motivations of the language user become more complex, functional communication is more and more affected by disturbances of the language code and its processors. Thus, though 'high-level' language-impaired patients may be able to function well in many settings, their language impairments can cause functional limitations that affect family and professional life.

This article should not end on this negative note. Rather, it is important to appreciate that many aphasic patients make excellent recoveries, for a variety of reasons. The natural history of many aphasic impairments is for considerable improvement, especially those due to smaller or subcortical lesions. Though still in their infancy, modern approaches to rehabilitation for aphasia are developing a sounder scientific basis. Technological advances allow for more professionally guided home training using computers, improved augmentative communication devices, and other useful support mechanisms. Support groups for patients and their families and friends are increasing in number; these help patients adjust to the changes in their lives and remain socially active. Though aphasia deprives a person of an important function to a greater or lesser degree, reactions to aphasia are as important as the aphasia itself in determining functional outcome and many aphasic patients function in vital ways after their loss. Lecours et al. (1983) cite a patient described by the Soviet psychologist A. R. Luria, who continued to compose music after a stroke that left him very aphasic; some critics thought his work improved after his illness. Time, rehabilitation, support, and a positive attitude can allow many aphasic patients to be productive and happy.

Abstract

An appeal is a proceeding in a court of law initiated by a party contending that a judgment of a subordinate court or agency is erroneous. Appeals are not universal in all legal systems, although they tend to be characteristic of many court systems, including the American court system. Contemporary American practice took its present form in the federal courts and in the courts of the states over the course of the nineteenth century. The most important general traits of the American appellate system are six principles of restraint, expressing deference to the judgment of the lower court or agency.

An *appeal* is a proceeding in a court of law initiated by a party contending that a judgment of a subordinate court or agency is erroneous. The appeal as it is known in western legal systems appears to have originated in the early Byzantine Empire. Today, although not universal in all legal systems, appeals exist in many court systems around the world, including the American court system. Contemporary American practice took its present form in the federal courts and in the courts of the states over the course of the nineteenth century – though these practices have shifted as the judiciary has faced a significant increase in workload over the past few decades. Still, the most important general traits of the American appellate system remain. These include six principles of restraint, enumerated below, expressing deference to the judgment of the lower court or agency.

Appeal is to be distinguished from other proceedings initiated in courts for purposes other than the correction of error by a subordinate court or agency. It is also to be distinguished from review proceedings conducted without regard for any previous disposition by the subordinate court or agency, as where a case is subjected to *trial de novo* in the higher court. The latter form of proceeding is, for example, standard practice at the first level of review in Germany (Meador et al., 2006; pp. 907–928). (It is not unknown in the United States; its use is most common when a higher court is reviewing the judgment of a small claims court, in which professional lawyers seldom represent the parties and the judge may be a nonprofessional.) Appeal is also to be distinguished from the *discretionary review* that may be observed in the Supreme Court of the United States and most other highest courts of states or of large nations. A court performing discretionary review may select the issues or rulings that it chooses to review; its primary purpose in making its selection is to explain the correct resolution of issues that are likely to recur in the lower courts or are otherwise important to persons other than the parties. In the United States and in many other countries, most appeals are taken to intermediate courts that are subject to discretionary review by courts of last resort. This article is an account only of the principles governing such appeals, primarily in the intermediate courts of the United States. Some variations in other systems will be noted, but those variations are so numerous that they defy synthesis.

Not Universal

The appeal is not a universal feature of legal systems. Some tribal courts, for example, bring to bear in the first instance most of the wisdom and authority of the community (see, e.g., Gluckman, 1955). There is then no body of higher persons to whom an appeal might appropriately be addressed. Also, there are autocratic systems, generally those having strong religious roots, in which an individual chief, priest, or judge is accorded the power of decision without possibility of review. Islamic law is noted as an example; the *kadi* administers an elaborate code of conduct contained in holy writ that no mere lawyer can presume to interpret, and the *kadi's* decision is not subject to review (Shapiro, 1980).

Although not universal, the appeal is a central feature of many court systems throughout the world today. To name just a few, countries including Canada, the United Kingdom, France, Italy, Germany, Israel, Japan, Brazil, South Africa, and the United States all have legal systems that include at least one (and often more than one) appellate court. The nature of appeals in these different countries varies considerably, depending upon whether appeals may be taken by right or by permission of a court, and whether the appellate courts consider general or specialized subject matters. There are, however, key similarities; typically in those systems using appeals, the review is conducted by a larger bench of judges than the court whose judgment is under review. In the United States, there is with rare exception a single judge presiding over a trial court from whose decisions an appeal may be taken to a three-judge court. Judges sitting on an appellate court are generally designated as persons of higher rank, and are likely to receive marginally higher salaries than judges sitting on the trial courts they review.

On the matter of whether appeals exist as a matter of right, even in the United States, the right of appeal in a civil case is generally a matter of legislative grace. Additionally, until 1888, there was no appeal from a criminal conviction in a federal court, even if the convicted person was subject to capital punishment (Frankfurter and Landis, 1928). However, the constitutions of some states have long guaranteed the right of appeal in criminal cases. Furthermore, it is still the law in all American jurisdictions that a state may not appeal a judgment of acquittal in a criminal case because a second trial would place the defendant in double jeopardy of conviction.

However, some states, such as New York, permit the state to appeal the legal basis for the acquittal in a proceeding that does not affect the present defendant but will serve as precedent for future cases.

Before the right to appeal became widespread, trial judges were seen to accumulate excessive discretionary power over the individuals engaged in disputes brought before them and on occasion to engage in seemingly lawless behavior. The Congress of the United States and state legislatures in the past century were attentive to the importance of constraining that discretionary judicial power and provided for appellate review in civil cases and in criminal cases not resulting in judgments of acquittal.

Principles of Restraint

The development of the appeal in American courts has resulted in the formulation of principles of restraint that are also in use in various forms in other legal systems. The institution described here is analogous to the *writ of error* familiar to ancient practice of English common law courts as an instrument for bringing a local one-judge decision to the attention of the larger court sitting in Westminster, but it departs from that usage in important respects. Contemporary American practice took its present form in the federal courts and in the courts of the states over the course of the nineteenth century. Six principles of restraint emerged.

Reversible Error: The Adversary Tradition

The first of these is the concept of *error*, a principle rooted in the Anglo-American adversary tradition placing primary responsibility for the conduct of litigation on the parties and their counsel. Because the burden is on the parties to present the evidence and inform the court of their claims or defenses, it is not generally error for a court to fail to identify a fact not proven or to fail to enforce a legal principle not invoked. The political function of this principle is to reduce the role of the court: disappointed parties often share responsibility for their own defeats. The administrative purpose of the principle is to encourage thorough preparation and presentation of the case by counsel and to protect the court from being trapped by deceitful or negligent counsel. It follows from this principle of reversible error that an appellant, to be successful on appeal, must generally point to a ruling made by the lower court to which the appellant made timely *objection* (Tigar and Tigar, 2011). In times past, it was often required not only that there be an objection to the erroneous ruling, but also that an appellant have taken *exception* to the adverse ruling, thus putting the trial judge on notice that the ruling may be challenged on appeal. The requirement of an exception has been eliminated from the practice of federal and most state courts.

Even in American courts, the requirement of a timely objection is sometimes disregarded for erroneous rulings so egregious that the judgment under review deeply offended the appellate court's sense of propriety. Such errors are denoted as *plain errors*. Rarely is the plain error doctrine invoked because it allows counsel to proceed in a no-lose situation, knowing that if the error is not corrected by the trial judge there will be a successful appeal affording a nonobjecting party with a fresh start. On the other hand, appellate courts may be reluctant to punish a party having a clearly meritorious claim or defense for no reason other than a lapse on the part of counsel.

Harmless Error

A second and more universal requirement is that no error, however egregious, is an occasion for reversal unless it was consequential. The familiar expression is that a *harmless error* is not grounds for reversal. Thus, an appellant who should and would have lost on other grounds cannot secure relief from an adverse judgment, even if that party can identify blatant errors of fact or of law that were committed by the court below and to which timely objection was made. This requirement conserves judicial resources; cases will only return to the trial court if there is some chance that they will result in a different outcome.

Standing to Appeal

A third requirement is *standing* to appeal. Generally, only a party who has participated in the proceeding is bound by the decision below. Hence, nonparties are not directly harmed by a judgment, even though they may strongly disapprove of the outcome and assert that a grave injustice has been done. The requirement of standing may be extended to bar appeal by nonparties who are only remotely affected by a judgment. Thus, investors or employees lack standing to appeal a judgment rendered against a corporation in which they own shares or are employed. The decision to appeal a judgment rendered against a corporation usually resides exclusively with those who may speak for the corporation itself.

Ripeness for Review

A fourth common requirement is that of ripeness for review. In general, an appeal is premature until a *final decision* has been reached in the court below. This is another principle of economy. An error of the lower court may turn out to be harmless; the higher court cannot know until a final decision has been reached. Moreover, there would be serious inefficiency if every litigant adversely affected by a provisional ruling of a trial court were allowed to take an immediate appeal. Not only would this afford parties a means of imposing needless financial costs on adversaries, but it would also force the trial court, or perhaps even the appellate court, to decide in each instance whether the lower court proceedings should be stayed pending the outcome of the appeal. If a stay is granted, the appellant has been empowered to delay the proceeding; and the delay itself may often result in injustice. If a stay is denied, there is the risk that further proceedings will be set aside as a result of the interlocutory decision of the higher court.

Most jurisdictions have numerous exceptions to the ripeness requirement. For example, in the federal practice, an *interlocutory appeal* may be taken from the grant or denial of a preliminary injunction for the reason that an error in such a ruling can have grave consequences for the party adversely affected (Steinman, 1998). Immediate appeal may also be allowed with respect to rulings involving substantial procedural rights that are very likely to affect the outcome of

a case. With respect to important issues of judicial administration, it may be said that an otherwise unripe appeal should be entertained in order to sustain the supervisory power of the appellate court, that is, to prevent lawless behavior by a trial judge. Appellate courts in the United States also have the power to issue several *extraordinary writs*, such as a writ of *mandamus* (a tool of Roman origins), to forestall an abuse of discretion by a subordinate court. In addition, a lower court may be permitted to circumvent the requirement of ripeness on its own motion by certifying to a higher court a question of law to which the lower court has no answer and that is central to a lengthy trial.

The Record on Appeal

A fifth concept shared by all American and most other jurisdictions is that of the *record on appeal*. The record is an official account of the proceedings below, or at least that part of the official account that the lawyers deem pertinent to the issues raised on appeal and therefore worth the cost of reproduction. The record is generally produced by the clerk of the court below and will contain documents filed with the court and a transcript of any oral proceedings prepared by a professional court reporter. In a civil case, the appellant must generally advance the cost of preparing the record, but a state may be required to bear the cost in a criminal case if the convicted person is indigent.

In general, an appellate court will not consider information that is not contained in the record (Marvell, 1978). There is an exception to this principle generally known as the *judicial notice* doctrine. A court may without proof take notice of common knowledge not contained in the record, or knowledge that is readily available to all, such as the day of the week of a particular date. Further, appellate courts frequently accept submissions from third parties known as *amici curiae*, whose representations of general facts, if uncontroverted, are sometimes relied upon despite being outside the record of the trial court (Gorod, 2011).

Deferential Review of Factual Determinations

Finally, there is a principle of deference to trial courts and agencies. Among the aims of this principle are to dignify the proceedings below and to discourage appeals challenging the guesswork inevitably done in the trial court to resolve issues on which there is conflicting evidence. The principle is expressed in an elusive distinction between *law* and *fact*. It is generally agreed that trial courts are entitled to no deference in their rulings on questions of law. Such rulings may be embodied in the *instructions* on the law given to a jury, or if there is no jury demanded, in the *conclusions of law* stated by the court to explain its disposition. An error in either statement may be a sufficient ground for reversal.

On the other hand, trial courts having dealt directly with the evidence submitted by the adversaries are extended the benefit of some doubt with respect to the determinations of fact. The appellate court hears no witnesses and sees only a transcript of the testimony. If the trial court judgment rests on a *jury verdict*, the factual determination in a civil case can be reversed on appeal only if the appellate court finds that there is no *substantial evidence* in the record to support it. In the absence of a jury, a trial judge's decision on evidence will in a civil case be expressed in the judge's *findings of fact*; such findings may be reversed in American courts only if the reviewing court finds *clear error*. It is generally assumed that the latter is a lower standard and that fact finding by a judge is more closely scrutinized on appeal than is fact finding by a jury.

The distinction between fact and law is subtle and even sometimes circular; a much-simplified summary is that issues of fact are those involving specific past events about which there is doubt, whose resolution has little or no bearing on future cases. Issues of law are typically those involving an interpretation of legal texts; but it is often said that whether there is evidence sufficient to support a jury verdict is itself a question of law. All that this means is that sufficiency of the evidence is a question in the first instance for the trial judge but that the ruling on the issue will be reviewed without deference. It is therefore not wrong to say that an issue of fact is simply one that the courts leave for decision by a trier of fact, while an issue of law is any issue that the appellate court chooses to decide on its own.

This distinction is not made in some other legal systems. For example, it is unknown to Japanese practice, which is modeled on the French. It is generally less useful in systems placing heavy reliance on written submissions of evidence. In such systems, the appellate court has access to the same information as the trial court, and hence there is less reason for deference to the judicial officer who saw and heard the adversary presentation of the parties.

Abuse of Discretion

Notwithstanding these settled principles of restraint, an appellate court is also empowered to correct discretionary actions of a trial judge that it deems to be an *abuse of discretion*. This principle is most frequently invoked to challenge and correct procedural rulings that are seen to be idiosyncratic or manifestly unjust (Friendly, 1982).

Appellate Procedure and Practice

In addition to these principles of appellate jurisdiction, American courts share a traditional procedure that is replicated in many legal systems. Until about 1960, this process was universal in the United States, and included (1) the submission of written *briefs* prepared by counsel on both sides that present their legal arguments and provide citations to pertinent legal texts and authorities; (2) an *oral argument*, at which counsel might engage the appellate judges in dialogue and answer questions they might pose; (3) a conference of the judges responsible for the appellate decision; and (4) a published *opinion of the court* explaining the legal principles underlying the disposition on appeal. Many of these procedural amenities have since been foreshortened in most American appellate courts as their caseloads have grown (Levy, 2011). Specifically, the majority of appeals in the federal courts of appeals do not receive oral argument and do not result in published opinions. It has also become common, especially in federal appellate courts, for

much of the responsibility to be delegated to law clerks and central staff attorneys. As the caseload has grown, it has been argued that the right of appeal should be abolished in federal practice, in recognition of the reality that many appeals are never seriously studied by the judges commissioned as members of the court (e.g., Parker and Chapman, 1997). Others have resisted this trend (Arnold, 1995). It has even been contended that the erosion of appellate procedure has diminished the *raison d'être* of the federal appellate courts (Carrington, 2000). Still, even in their constricted form, the American appellate courts continue to develop the law and correct errors in tens of thousands of cases each year.

Appeasement: Political

This article is a revision of the previous edition article by D.W. Larson, volume 1, pp. 589–592, © 2001, Elsevier Ltd.

Abstract

Appeasement is a policy by which a state hopes to avoid war (or achieve other goals) by making concessions to an adversary, thereby eliminating its grievances. For many years after the failed attempts by Britain and France to conciliate Nazi Germany during the 1930s, appeasement was regarded as being futile, dangerous, and immoral. The so-called 'lessons of Munich' exercised a profound influence on foreign policy, especially in the United States, for more than a generation. More recently, however, scholars and policymakers have come to recognize that appeasement can, in certain circumstances, be an effective and appropriate strategy.

Defining Appeasement

In classical European diplomacy, appeasement meant the "reduction of tension between [two states] by the methodical removal of the principal causes of conflict and disagreement between them" (Craig and George, 1990: 250). The strategy involved making concessions to one's adversary, and some definitions thus emphasize this aspect of the policy (Ripsman and Levy, 2008). Terms frequently associated with appeasement or used as synonyms for it include 'inducements,' 'positive sanctions,' 'conciliation,' and 'accommodation.'

Prior to World War II, the word 'appeasement' had a neutral or even positive connotation. Historians Paul Schroeder (1976) and Paul Kennedy (1983) have identified a tradition of appeasement in British foreign policy dating back to the 1860s, noting that the strategy was employed as a means of settling disputes between Britain and rising powers seeking a greater share of the world's territory and resources. For British statesmen, appeasement was a pragmatic policy of realpolitik aimed at maintaining the balance of power and avoiding war over issues that did not threaten their country's most vital interests. It was also a just and honorable policy that admitted and sought to satisfy an adversary's legitimate grievances.

The meaning of appeasement changed dramatically with the experience of the 1930s. The disastrous attempts of the British government and especially Prime Minister Neville Chamberlain to accommodate the Nazi German government of Adolf Hitler caused the strategy to fall into disrepute. Shortly after World War II, international relations theorist Hans Morgenthau (1951: 137) termed appeasement "politically unwise," adding that appeasement occurs "when a nation surrenders one of its vital interests without obtaining anything worthwhile in return." Others came to regard the policy as being not merely unwise, but immoral.

Munich and the 'Lessons' of the 1930s

Beginning in the mid-1930s, Britain and France pursued an appeasement policy with respect to Nazi Germany, which each conceived as the principal long-term threat to its security. Initially, the strategy was largely passive. Thus, the two Western powers acquiesced to German violations of the Treaty of Versailles, including the remilitarization of the Rhineland in 1936. While this aspect of the policy never disappeared – it is reflected, for example, in the failure to act in the face of the 1938 Anschluss with Austria – the British government subsequently adopted a more active approach, trying to negotiate both economic and territorial arrangements with Germany that would allow for the preservation of peace. British policymakers were particularly hopeful that they might maintain the political and territorial status quo in Europe by redrawing the colonial map of Africa in a manner that was more favorable to German interests.

The famous conference between Neville Chamberlain and Adolf Hitler at Munich in September 1938 is widely regarded as the epitome of appeasement. By agreeing to cede the Sudetenland region of Czechoslovakia to Germany, Chamberlain hoped that he had satisfied Hitler's territorial ambitions and preserved peace. Unfortunately, he had not. In March 1939, Germany seized the remainder of Czechoslovakia, and in September it invaded Poland, despite promises by Britain and France to intervene.

The Munich Conference and subsequent events had a profound effect on both international relations theory and policymaking. After Munich, appeasement was judged to be both futile and dangerous. It was futile because aggressors could not be satisfied; indeed, by feeding them, one only increased their hunger for territory. As the French proverb says, 'L'appetit vient en mangeant' – 'appetite comes (or grows) with eating.' It was dangerous because it undermined subsequent attempts at deterrence. The Germans, having been handed the Sudetenland and allowed to take the rest of Czechoslovakia, did not believe French and British threats to defend Poland, even though Britain had issued a 'guarantee' to do so and had later joined Poland in a formal treaty of mutual defense.

Scholars, particularly in the United States, took what they believed to be the lessons of the 1930s and developed the deterrence model of international politics (Jervis, 1976). This model holds that, when facing an aggressor, credible threats of retaliation are necessary to deter attack and prevent war. U.S. policymakers relied heavily on this model in developing national security policy during the Cold War. It formed the basis of America's strategy of containment vis-à-vis the Soviet

Union, prescribing a massive arms buildup as well as military intervention in places of little strategic or material value to the United States for the purpose of maintaining credibility in other, more vital locations. The wars in Korea and Vietnam were fought not so much because the United States had vital interests in these regions, but because U.S. policymakers feared that Soviet and other communist leaders would not believe their threats to defend Western Europe if they failed to respond to provocations in Asia.

Since the end of the Cold War, far lesser menaces than the Soviet Union and international communism have been viewed by U.S. leaders through the lens of the 1930s. When Iraq invaded and conquered Kuwait in August of 1990, the administration of President George H.W. Bush quickly invoked the so-called Munich analogy, comparing Iraqi leader Saddam Hussein to Hitler in arguing that Iraq could not be allowed to retain Kuwait because doing so would only encourage further Iraqi aggression. Indeed, in the United States, appeasement continues to own such an odious reputation that the label is still employed frequently and almost indiscriminately by politicians and pundits seeking to discredit diplomatic initiatives to which they object.

Challenging the Conventional Wisdom

Although in much of popular and political discourse appeasement remains in disrepute, within the scholarly community the conventional wisdom concerning appeasement has been repudiated to a considerable degree. Some historians have challenged the notion that Hitler regarded the Munich Agreement as a great diplomatic victory, arguing instead that he considered it a crushing defeat, having been thwarted in his desire to take the Sudetenland by force. They contend that Hitler, having accepted Chamberlain's offer and stepped back from the brink of war, began to doubt his own – not his enemies' – fortitude and courage. Hitler, in this view, found Anglo-French threats to defend Poland credible, but decided to invade, anyway, determined, after Munich, not to back down again (Weinberg, 1980). Other scholars suggest that to the degree that Hitler found Anglo-French threats not credible, this may have been due to his own motivated bias – wishful thinking – rather than previous behavior by Britain and France (Rock, 2000).

Students of international politics have cast serious doubt on the belief that appeasement is dangerous because it undermines subsequent efforts at deterrence. This belief rests on the assumption that policymakers base predictions about a state's future behavior on its past actions. But according to Jonathan Mercer (1996: 227), "decision-makers do not consistently use another state's past behavior … to predict that state's behavior." Daryl Press (2005) tests what he calls 'past actions' theory against 'current calculus' theory and concludes that states typically do not assess the credibility of deterrent threats on the basis of a state's past behavior; instead, they rely on an analysis of current factors and conditions, including the perceived military balance.

Finally, researchers have challenged the view that appeasement as a diplomatic strategy is doomed to failure (Rock, 2000). Cases of successful appeasement exist. Of these, perhaps the most notable is British conciliation of the United States during the last decade of the nineteenth century and the first decade of the twentieth century. At this time, Britain's security position was precarious. In Europe, it faced a hostile France and Russia, along with a rapidly rising Germany. In the Western Hemisphere, it confronted the United States, like Germany a late industrializer and growing maritime power, but with far greater potential, given its geographic position, population, and natural resource base. Beginning in late 1895, the United States began to assert itself against British interests. Invoking the Monroe Doctrine, it claimed the right to intervene in a dispute between Britain and Venezuela concerning the boundary between Venezuela and the colony of British Guiana. Although the British government initially rebuffed U.S. overtures, once a crisis erupted and war seemed possible, it quickly reconsidered and agreed to submit the matter to international arbitration.

In subsequent years, additional disagreements were resolved in a similar manner. Under pressure from the U.S. government, British leaders abandoned the Clayton–Bulwer Treaty, renouncing their right to a voice in the construction of a canal through the Central American isthmus. They agreed to submit a dispute concerning the boundary between Alaska and the Canadian Yukon to a panel of six impartial jurists, three from the United States, two from Canada, and one from Britain. When U.S. President Theodore Roosevelt stacked the panel, the British government swallowed hard and accepted his appointments. Then, when it appeared that the panel might be deadlocked, the British representative sided with the Americans against his Canadian colleagues. Between 1904 and 1906, Britain withdrew its naval forces from the Americas, effectively ceding control of the Western Hemisphere to the United States.

The wisdom of Britain's appeasement strategy is evident in hindsight. By placating the United States, British leaders avoided a war that would have been ruinous economically and militarily, one that Britain might well have lost. Having also achieved a rapprochement with France and Russia, British policymakers freed themselves to concentrate on their most dangerous foe: Germany. And, ultimately, they gained an ally, with the United States fighting on Britain's side in World War I. It is nearly impossible to imagine such a favorable outcome had Britain elected to pursue an unyielding, hard-line policy.

When Does Appeasement Work?

Since the historical record of appeasement is mixed, it is important to understand the conditions under which it succeeds and fails. To do so requires specifying the goals that appeasement might be expected to achieve. Traditionally, the policy has been regarded as being aimed at the avoidance of war. But, in the case of Britain and the United States, avoiding war was only the minimum aim for British leaders. Their maximum aim was considerably more ambitious: to make a friend or even an ally of the United States. Generally, the objectives of appeasement may differ according to time horizon (short-term vs long-term) and whether they aim at maintenance or alteration of the international status quo. As a short-term strategy, appeasement may seek to resolve a crisis or result in a limited political trade. As a long-term approach, it

may seek crisis prevention or to produce friendship or alliance. For the most part, these goals are not mutually exclusive. As the Anglo-U.S. case demonstrates, an appeasing state may have both short-term (crisis resolution) and long-term (friendship/alliance) objectives (Rock, 2000).

Appeasement, when it succeeds, may do so via multiple mechanisms. The dominant method, at least according to the conventional wisdom, is satiation: the satisfaction of the (usually territorial) demands of a revisionist state. However, British policymakers during the 1930s had at least three other mechanisms in mind as they sought to conciliate Nazi Germany. One of these was reassurance: an effort to increase an insecure state's confidence in its security position. A second was socialization: an attempt to teach belligerent, bumptious German leaders how to behave in polite, international society. The third was manipulation of Germany's internal political balance. Believing that Germany was not a monolithic state and that there existed a powerful group within the German government that favored peace, the British government sought by means of concessions to strengthen the hand of supposed German moderates in opposing Hitler's bellicose policies (Rock, 2000).

Whether or not appeasement succeeds depends on whether or not these mechanisms are effective in a given case. Perhaps the most critical factor is the nature of the adversary. War-seeking states cannot be appeased because concessions do not address their primary objective: entry into armed conflict. Indeed, as the Munich experience demonstrates, inducements (particularly offers that cannot be refused because they grant what a state claims to be seeking) only serve to frustrate such states and their leaders by delaying the accomplishment of their intended purpose. By contrast, greedy states with limited, tangible ambitions can be appeased. The same is true of states that are insecure. The former can be satiated, while the latter can be reassured. The United States, at the turn of the twentieth century, was a state both greedy and insecure. British concessions satisfied America's limited territorial ambitions (and the country's desire for recognition as the dominant power in the Western Hemisphere) while simultaneously alleviating U.S. concerns about Britain's intent to expand its empire in Latin America. There is no evidence, contrary to the conventional wisdom regarding appeasement, that Britain's inducements caused the United States to enlarge the scope of its aims or to become more aggressive in its pursuit of them (Rock, 2000).

A second factor that helps to determine the success or failure of appeasement is the nature of the inducements offered by the appeasing state. In order to be effective, concessions must be properly directed – that is, they must address the needs or demands of the target state. Early British efforts to conciliate Germany, such as allowing German rearmament in violation of the Treaty of Versailles, did not address Germany's territorial ambitions, although they did, counterproductively, enhance Germany's prospects for achieving these ambitions through the use of force. Concessions must also be sufficient in the sense that they must be adequate to satiate (or reassure) the target state. Britain's willingness to redraw the colonial map of Africa, for example, did not come close to satisfying Hitler's ambitions, which lay mainly in the continent of Europe. By contrast, British concessions to the United States directly and fully addressed U.S. needs and wants. Finally, concessions must be properly perceived by the target state. Perception depends both on the transmission of signals and on their reception. U.S. efforts to conciliate Saddam Hussein's Iraq in the years leading up to the Iraqi invasion of Kuwait were thwarted in part by Congressional attempts to impose economic sanctions in response to Iraqi human rights abuses, as well as anti-Iraqi sentiments expressed by other organs of the U.S. government, including the Department of State. The U.S. government sent mixed signals that were difficult for the Iraqi government to interpret. On the receiving end, in some cases, the offer of inducements is perceived as not being genuine, or even as a trick; in others, the message of conciliation is lost in the flow of diplomatic exchanges (Rock, 2000).

A third factor that helps to explain the success or failure of appeasement is the existence (or lack thereof) of incentives external to the relationship between the appeaser and the target state for the latter to accept and be satisfied by the concessions that are offered. Such factors may be international – e.g., the presence of a foreign adversary against which the cooperation of the appeasing state might be valuable. They may be internal – ideological, political, or economic reasons for the state to decide that abandoning a rivalry would be advantageous to it. One can see such factors at work in the U.S. decision to accept British concessions in the late nineteenth and early twentieth centuries. The United States faced what it perceived to be a serious security threat from Germany, which better relations with Britain would alleviate. It also possessed strong cultural reasons (in the form of Anglo-Saxon nationalism), political/ideological reasons (in the form of shared liberal values and democratic institutions), and economic reasons (due to a high level of commercial and financial interdependence) to respond positively to Britain's overtures (Rock, 2000).

Why Do States Choose Appeasement?

Appeasement is a policy adopted by states in dealing with a threatening or potentially threatening adversary. It is not, however, the only option available. Rather than seeking to redress an opponent's grievances, a state may choose to stand firm, rejecting the demands that are placed on it and attempting to defend its interests by upholding the balance of power, maintaining a posture of deterrence, and, if necessary, going to war. Why do states in some instances choose appeasement over what might be regarded as the preferred option, one that, if successful, enables a state to uphold its interests and maintain its international position?

During World War II and immediately thereafter, the answer to this question typically took the form of the so-called guilty men thesis. Taking its name from the title of a devastating if not entirely accurate polemic published pseudonymously in 1940 by opponents of British appeasement, the essence of this explanation is that the policy was undertaken by leaders who were too weak and pusillanimous to confront an aggressor or too feeble-minded and foolish to understand what was at stake (Cato, 1940). Neville Chamberlain, who was singled out for particular criticism, and many of his colleagues in the British government were vilified and are sometimes still vilified as the embodiment of this sort of leader.

With the benefit of temporal distance from the failures of the 1930s, scholars began to take a more dispassionate approach to the matter. It is now well understood that a balancing strategy may not always be feasible. External balancing, which involves reliance on other states, requires the availability of powerful allies. Internal balancing, which involves the mobilization of domestic resources, demands the production of armaments, an increasingly large military force, and ultimately the commitment of extensive economic and physical assets.

Beyond the matter of feasibility, there are other reasons that states may appease rather than balance or deter. Potential allies may be rejected because they are deemed to be unsuitable by political leaders or public opinion. The citizenry of a country may be opposed to preparations for war, fearing that they indicate the intention of the government to become involved in one. Because internal balancing is expensive, it may not be possible for a government to pursue simultaneously a balance-of-power or deterrent strategy and satisfy its (and its supporters') domestic welfare aspirations. National leaders who cannot provide both guns and butter at the same time must choose between them, and domestic political calculations flowing from the desire to remain in power may push them in the latter direction (Trubowitz and Harris, forthcoming).

Britain's decision to appease Nazi Germany during the 1930s reflected many of these factors. For the British government, the most essential allies were not available. France, having been devastated in World War I, had scant desire to confront Germany. The United States, wary of European entanglements, was profoundly isolationist. Even the British dominions favored appeasement. And the Soviet Union was rejected as a potential ally because the British government (with some justification) deemed it to be untrustworthy.

If effective external balancing seemed impossible to British leaders, internal balancing appeared scarcely less so. Britain was a relatively small country with a limited population and resource base. Its economy had suffered greatly as a result of World War I and the Great Depression. Chamberlain and the Conservative Party more generally had staked their electoral prospects on domestic reforms and economic recovery. To choose guns over butter – a choice could not be avoided, since Britain could not afford both – would have been unpopular and politically problematic. Beyond this, the so-called anti-appeasers were unable to unite in support of an alternative policy. Given the international and domestic environments in which the Chamberlain government was operating, it is hardly surprising that it opted to pursue a strategy of appeasement (Trubowitz and Harris, forthcoming).

In grand strategic terms, appeasement is mainly an alternative to balancing. However, appeasement can also be an essential component of a state's efforts to maintain a favorable balance of power. This is true most obviously when a state decides to appease one adversary in order to focus its attention on another, as when Britain elected, prior to World War I, to accommodate the United States partly in order to confront more effectively the danger from Germany. Appeasement may also serve tactical purposes consistent with balancing. For example, if the intentions of an adversary are unclear, appeasement may enable a state to test and clarify them. This was one motivation for Britain's appeasement policy during the 1930s. More importantly, perhaps, appeasement may buy time so that an unprepared state may ready itself to meet a foreign threat on the field of battle. Ripsman and Levy (2008) argue that British leaders, convinced that they were in a position of relative weakness, sought to appease Germany in order to delay war until Britain had rearmed.

The Ethics of Appeasement

Following the failure of Munich, appeasement rapidly acquired a reputation as a morally suspect, if not altogether bankrupt policy. Chamberlain's decision, made with the support of French President Edouard Daladier, to abandon the Czech government and cede the Sudetenland to Germany in an attempt to pacify Hitler seemed in retrospect unconscionable. Although none other than Winston Churchill wrote after the war that "appeasement in itself may be either good or bad depending on the circumstances," his was a view not widely shared (Record, 2005: 1). In 1956, Webster's offered this definition of appeasement: "To conciliate by political, economic, or other considerations; now usually signifying a sacrifice of moral principle" (Herz, 1964: 298).

The moral status of appeasement, however, merits a more thorough consideration than it has usually been given. Inasmuch as a state's right to individual and collective self-defense is generally acknowledged by scholars and enshrined in international law, there would seem to be few situations in which appeasement would be obligatory. Helen Frowe (2011: 39) suggests that appeasement might be required when the harm that would be produced by it is not serious, but she notes, "it will almost never be the case that appeasement of aggression between states avoids serious harm." Michael Walzer (2006: 51) is more definitive, writing that those confronted with aggression are "always justified in fighting." Pacifists typically accept that aggression may be resisted; they differ from non-pacifists in insisting that resistance must not involve the use of deadly force (Holmes, 1989). Given the apparent consensus that appeasement is rarely, if ever, required; the more interesting question is whether or not it is morally permissible.

One argument against appeasement is that it violates a duty to resist evil. According to Andrew Bacevich, neoconservative critics of appeasement in the United States have drawn two lessons from the 1930s. First, "that evil is real." And, second, "that for evil to prevail requires only one thing: for those confronted by it to flinch from duty" (Bacevich, 2005: 73). To condemn appeasement as a failure to resist evil, however, requires one to assume that an adversary's grievances or demands are never legitimate and that there are never other evils more worth resisting. That these assumptions are valid is not self-evident. Indeed, during the 1930s, many British policymakers explicitly rejected them. They saw as their primary responsibility the avoidance of another bloody, financially ruinous war. Moreover, they did not regard German demands as illegitimate, believing that Germany deserved relief from the onerous burdens of the Treaty of Versailles and that the right of self-determination for the Sudeten Germans and other ethnic Germans living outside of Germany should be upheld. Had their policy succeeded, Chamberlain and his colleagues might today be applauded for their principled stance. Although they

failed, it is hard to see how a duty to confront evil could rule out appeasement in every case.

A second, more plausible argument against appeasement is that it violates a duty to defend. Is it morally permissible for one state to refuse to defend another, especially when the latter is incapable of defending itself? This is the question posed by the British cession of the Sudetenland to Germany in 1938. It seems evident that had Britain been bound to Czechoslovakia by a formal, contractual agreement (i.e., a treaty of mutual defense), then it would have been obligated to defend the Czechs. But no such agreement existed. Any obligation must therefore have come from Britain and Czechoslovakia's shared membership in an international community of states in which the members had reciprocal rights – above all, territorial integrity and sovereignty – and duties, including a duty of collective security. Whether or not an international community existed in the late 1930s, particularly following the collapse of the League of Nations, may be debated. In the twenty-first century, with a more robust United Nations claiming almost universal membership, such a notion, associated with what one scholar calls the 'state-moralist' position, would seem easier to sustain. The rise of a 'cosmopolitan' school of thought, which posits the existence of a global community of human individuals, rather than of states, may make the idea of moral responsibilities beyond one's own borders still more plausible (Nye, 1986).

The issue nonetheless remains complicated by the fact that states have competing moral responsibilities: to the governments and peoples of other states, but also, and perhaps primarily, to their own citizenry. Was it not the first duty of British leaders at the time of Munich to protect the lives and welfare of the British people rather than the sovereignty and territorial integrity of the Czech state? Neville Chamberlain appears to have believed that it was. So, too, did the British public, judging by the adoring crowds that greeted the prime minister on his return from Germany. The British government failed to understand that the interests of Britain's citizens might have been better defended at Munich by fighting for Czechoslovakia rather than by acquiescing to Hitler's demands, but this does not necessarily mean that its priorities were misplaced.

Beyond the question of whether or not a state must defend another, there is the issue of whether or not it is morally permissible for a state to refuse to defend itself, to appease a potential aggressor by sacrificing its own territory, population, or resources – at the extreme, by sacrificing its independence – by declining to engage in armed combat. Utilitarian reasoning suggests that under some circumstances, it may be. When armed resistance is futile, the harms of war and forcible submission are almost certain to exceed the harms associated with surrender (Orend, 2013). In such situations, it would seem better to accede to the adversary's demands than to resist. The eminent just war theorist Michael Walzer (2006) concedes the force of this argument. Nevertheless, he writes, "In most cases … fighting is the morally preferred response." "We want," he says, "to live in an international society where communities of men and women freely shape their separate destinies. But that society is never fully realized; it is never safe; it must always be defended" (51, 72). States must fight, even in the face of almost certain defeat; otherwise, the core values of the international community and the rights of states (and of individuals from which the rights of states are derived) will be diminished or lost.

Although he regards fighting as the morally preferred option in most cases, Walzer does not rule out appeasement in every instance. The obligation to fight existed with respect to Germany during the 1930s because Germany was "committed to the continual use of violence, to a policy of genocide, terrorism and enslavement" (Walzer, 2006: 69). It existed with respect to Stalinist Russia, which, like Germany, posed a fundamental challenge to international norms crucial to the rights of states and those living within them. Walzer suggests, however, that appeasement of a more conventional great power would be morally permissible as long as it did not "involve absolute subjection to the 'rule of violence'" (69). He must believe, therefore, that a state may also decline to defend itself and its interests against an adversary whose ambitions are less extensive and whose intentions are less malign.

Appeasement is inherently neither moral nor immoral; it must be evaluated on a case-by-case basis. In any given case, the moral permissibility of appeasement rests on a number of factors that include, but are not necessarily limited to, the following: (1) the legitimacy of the adversary's grievances and demands, (2) the harm produced by the concessions that are made, (3) the likely harm produced in the event that appeasement fails, (4) the likely harm produced by refusing to appease and adopting an alternative strategy (e.g., balancing, deterrence, war), and (5) the likelihood that appeasement will succeed. At one extreme, appeasement would appear to be justified in cases in which the adversary's grievances are legitimate, the harm resulting from concessions is small, the likely harm resulting from refusing to appease is large, the failure of appeasement is not likely to produce severe harm, and the prospects for successful appeasement are good. At the other extreme, appeasement would appear to be unjustified in cases in which the adversary's demands are not legitimate, the harm resulting from concessions is large, the likely harm resulting from refusal to appease is small, the damage from unsuccessful appeasement would be great, and the prospects for successful appeasement are poor.

By these criteria, Britain's late-nineteenth- and early-twentieth-century appeasement of the United States appears to have been justifiable, while its attempted conciliation of Nazi Germany during the 1930s appears to have been much less so. Of course, evaluating the morality of appeasement is relatively easy in hindsight, when outcomes are known. Political leaders confronted with the decision to appease or not to appease operate in an uncertain environment and must make calculations regarding the consequences that might ensue from whatever policy they choose. The moral status of their strategy cannot be evaluated by its results, which can never be entirely foreseen. It must be evaluated on the basis of whether or not the leaders' assessment of the situation and their calculations of likely outcomes seem reasonable or defensible, given the information available to them at the time.

Engagement: A Modern Form of Appeasement?

Appeasement is now considered by many scholars to be an effective and legitimate tool of statecraft under certain

circumstances. Practitioners of foreign policy largely share this view. They are careful, however, to refrain from using the term 'appeasement' because the word retains its odious reputation in the public mind and represents an easy target for political foes.

Since the 1980s, scholars and policymakers, particularly in the United States, have preferred to speak and write of 'engagement.' Engagement, by one definition, is "the use of non-coercive diplomatic tools and initiatives to elicit cooperative behavior from the target state." This is accomplished through: "(1) accommodation of the target state's interests (regardless of normative consideration); (2) an 'enmeshing' of the state in international institutions upon which its well-being becomes based; or (3) the growth of a variety of transnational linkages that transform the preferences of the state" (Cha, 1999: 36). The Ostpolitik of West German leader Willy Brandt during the 1960s is an example of engagement. More recently, U.S. administrations have pursued engagement with respect to the white-minority government in South Africa and with respect to Vietnam, North Korea, China, Iraq, and Iran, among other states.

Engagement strongly resembles appeasement as it was practiced in classical European diplomacy and by the British government during the 1930s. Johnston and Ross (1999: xii) argue that the two strategies differ in name only, having "identical policy options and objectives." Like appeasement, engagement aims at the reduction of tension. It "depends to a significant degree on positive incentives to achieve its objectives" (Haass and O'Sullivan, 2000: 113). It operates by means of satiation, reassurance, socialization, or alteration of an adversary's domestic political balance – or some combination of these.

There is thus considerable truth to the claim that engagement is "a modern form of appeasement" (Rock, 2000: 22). But the two are not exactly the same. Engagement can be a comprehensive strategy, operating on a variety of fronts. It may seek to maintain open lines of communication, cooperate in matters of mutual interest, and integrate an adversary into the international legal, political, and economic systems in order to gain leverage and constrain its behavior. Appeasement is generally narrower in scope, relying more heavily on inducements to satisfy grievances. It is perhaps most appropriate to think of appeasement as a type of engagement. Indeed, Randall Schweller (1999: 14) has written, "the most common form of engagement is the policy of appeasement."

Applied Criminology and Criminal Justice

Brian Stout and Kerry Clamp, School of Social Sciences and Psychology, University of Western Sydney, Penrith, NSW, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Applied criminology may be thought of as being concerned with the application of the discipline of criminology to 'real world' problems of crime and criminal justice. It is both critical and engaged and seeks to find solutions to particular issues of crime and justice, as well as to problematize suggested approaches. The article sets out to review and explore attempts to address crime, to deal with offenders, and to respond to victims.

Introduction: Applied Criminology: What Is It and How Does It Work?

This article is concerned with surveying the field of applied criminology or criminology in its applied form. Applied criminology may be thought of as being concerned with the 'real world' problems of crime and criminal justice and how the research and scholarship within the discipline of criminology can relate to them. It is influenced by both contemporary academic criminology, which seeks to explore and conceptualize crime, its causes, and the responses to it in theoretical terms, and administrative criminology, which has largely become an attempt to "implement pragmatic means of crime opportunity reduction and to manage crime through situational prevention measures" (Muncie, 1998: 4).

Applied criminology seeks to address and compensate for the perceived deficiencies of other criminological approaches. Academic or theoretical criminology is vulnerable to the criticism of being distant from real-world concerns and detached from the public, criminal justice agencies and practitioners. Administrative criminology can sometimes be atheoretical or uncritical, and it suggests that the causes of crime are relatively unimportant or politically impossible to tackle (see Young, 1988). Applied criminology can be viewed as an area of study, which not only seeks to find solutions to particular issues raised by crime and criminal justice, but also to problematize current and suggested approaches.

Applied criminology, as conceptualized by Stout et al. (2008), seeks to draw on both academic criminology and administrative criminology. Canton and Yates (2008: 5) define applied criminology as "a criminology which self-consciously and deliberately explores the insights of criminology for their relevance and application to policy and practice" and which "should have a critical edge, casting a discriminating, analytical gaze over the process of criminalisation, crime enforcement, and the criminal justice system" (2008: 6). Criminological research and theoretical knowledge has significant relevance for addressing crime, offending, and victimization, and the collection makes explicit the relationship between governmental agendas and knowledge production.

Criminology, in its applied form, should engage with real-world concerns but should not be simply pragmatic or functional. It should have a critical edge, casting a discriminating, analytical gaze over the process of criminalization, crime enforcement, and the criminal justice system. It should seek to expose the relationship between governmental agendas and knowledge production (Canton and Yates, 2008: 6). Although the term 'applied criminology' is a familiar one, appearing in the titles of courses, conferences, and research centers, it is not possible to claim that it is, in itself, a distinct area of criminology. It does not claim to offer major premises or unifying theories, which define crime, isolate the causes of offending, and offer a solution to the crime problem (such as critical criminology, peacemaking criminology, and so on). Applied criminology should be thought of as an approach, which not only seeks to find solutions to particular issues raised by crime and criminal justice through established criminological endeavors, but also to problematize current and suggested approaches embraced by governments and criminal justice agencies. It directly takes on the challenge implied in Loader and Sparks's (2010) conceptualization of criminology as a 'successful failure' – a discipline that is successful in attracting the attention of students and academics, but that has a declining influence outside the academy. Applied criminology addresses the practice implications of criminological scholarship.

With this orientation in mind, we use the term to discuss criminology that has a direct connection with the 'real' world and thus highlight the role that criminological research has had on shaping criminal justice and its responses to offenders and victims at a policy level. In their characterization of applied criminology, Canton and Yates (2008: 2) identify three principal questions, which they suggest that applied criminology should address:

- What is to be done about offenders?
- What is to be done about crime?
- What is to be done on behalf of the victims of crime?

This article uses a version of these questions, in a slightly different order, to outline how criminology is being applied to address each of these questions in turn.

What Is to Be Done about Crime?

A starting point for an account of the application of criminology is to take stock of the context of the understanding of crime. Until the early postwar period, criminology had been dominated by the positivist approach, which viewed the causes of crime as a consequence of one's circumstances and

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10512-4

neoclassicism, which was based on the belief that certain responses would reduce the likelihood of repeat offending. However, during the late 1960s and 1970s, respectively, the discipline underwent two major crises (Young, 1988). The first related to what Young (1988) referred to as the "aetiological crisis." For the most part, positivism was based on the belief that as social conditions improved, postwar crime would decrease. However, crime did not decline as many had suspected, instead it continued to rise. The second was a crisis of penalty following the publication of a number of police studies in the United States, which questioned the effectiveness of the police and the reformative potential of prisons in dealing with crime. This found expression in the 'nothing works' pessimism, discussed in the next section, and, coupled with increasing crime rates, led to questioning of the ability of the state to control crime (Garland, 2001: 62).

Many advanced liberal democracies responded to this perceived limitation by reforming criminal justice institutions and mobilizing nonstate mechanisms in the "fight against crime" (Crawford, 2008). The 1970s and 1980s were characterized by the revival of the 'just deserts' model, which focused on the punishment of the offense rather than on the needs of the offender; an increased role for both the victim and the 'community' in the administration of justice (rather than professionals only); and the 'politicization' of crime control in which 'public opinion' became a central issue. The rise of "populist punitiveness" (Bottoms, 1995) or the "law and order" ideology (Cavadino and Dignan, 2002) has often involved politicians talking tough and introducing ever more stringent penal policies in order to secure public support (Young and Matthews, 2003). Garland (2001: 172) succinctly describes this development as:

> Criminal justice is now more vulnerable to shifts of public mood and political reaction … The populist current in contemporary crime policy is, to some extent, a political posture or tactic, adopted for short-term electoral advantage.

This, unsurprisingly, has resulted in increased resources being devoted to policing, prosecutions, and prisons (Roach, 2005; McEvoy, 2007) as advanced liberal governments seek to demonstrate to their publics that they are able to control crime. A widespread fear of crime and the ability of politicians and the media to generate "moral panics" (Cohen, 1972) have made this a popular strategy for those wanting to serve vested interests. However, this has also had the adverse effect of dramatically increasing prison populations and creating a perception of increased criminal incidents, despite a relatively stable decline in crime rates in the decade since the mid-1990s (Cesaroni and Doob, 2003; Young and Matthews, 2003).

Many developed nations have therefore increasingly become aware that an exclusive adherence to a punitive strategy has not produced the desired result in terms of "greater satisfaction with criminal justice or an increased sense of security of justice" (Roach, 2005: 2). An increase in caseloads; a perceived lack in the ability of the criminal justice system to deal with crime effectively; and an increase in victim advocacy (Albrecht, 1999; Garland, 2001; Zedner, 2002; McEvoy, 2007) have therefore subsequently resulted in concerted efforts to find new and innovative ways of dealing with offenders and victims.

A highly visible attempt to reformulate the relationship between criminal justice and its public has been located within policing practice. The introduction of community-based policing, problem-oriented policing, and restorative policing during the 1980s and 1990s offered the police an alternative to the reactive, incident-focused style (Paterson and Clamp, 2012). Such initiatives acknowledge the central role of the community in identifying, reporting, and responding to crime, and it is thought that the police are more likely to successfully tackle crime where policing strategies are based within and informed by community members themselves. However, this ideological shift runs contrary to the historic policing mission where independent police professional knowledge directs local developments and it has thus generated a certain level of resistance by police officers. Alongside this, a body of critical literature has developed that questions the extent to which this shift in power and responsibility has, or even can, take place (Hobsbawm, 1995; Bauman, 2001). This literature questions whether placing 'the community' at the center of policing policy makes sense, especially during a historical period in which many communities (in their traditional sense) are understood to have disappeared (see Clamp and Paterson, 2011).

Criminology has also engaged with policing in questioning its very definition of crime and its approach to how offending is measured and recorded thus leading to high-profile and heated debates between police stakeholders and the academic community (Eterno and Silverman, 2012). It has often been the role of criminologists to hold the police to account and to strongly criticize police practice, when required, such as in the two high-profile British examples of the Hillsborough football stadium disaster (Scraton, 2009) and the murder of Stephen Lawrence (Bowling and Phillips, 2002). However, increasingly, across the world, the application of criminology to policing is taking place within police training with university-level preentry police training programs being offered in, among others, the UK, the United States, and Australia. Criminology can then play a dual role of an outsider, researching and commenting on practice, and an engaged insider, contributing to the development of the profession.

What Is to Be Done about Offenders?

Criminological research has informed debates in criminal justice with regard to the difficult question of what should be done with offenders. Criminological research has been applied in determining what approach should be taken in effectively rehabilitating offenders, but this issue has not always been simple or straightforward.

Discussions of the effectiveness of interventions with offenders conventionally start with the notorious meta-analysis of 231 cases (Lipton et al., 1975) and the conclusion from that analysis, most often associated with Robert Martinson, which almost nothing works with offenders. This research was often mischaracterized and was used for political purposes, by both left and right (Miller, 1989), but it provided an impetus for the lengthy and ongoing work of establishing what is effective in

working with offenders. Martinson himself later retracted his 'nothing works' conclusion and accepted that some things work in some circumstances (Martinson, 1979). Applied criminology has been concerned with determining what is effective in working with offenders. However, there are also arguments that simply asking 'what interventions are effective?' is misdirected and reductive; it is also important to take account of offenders' rights and of the narratives that offenders themselves relate about their desistance from offending.

Over the last decades, the question of 'what works' or what is sometimes known as 'effective practice' has dominated the application of criminology to work with offenders. Mackenzie (2000) summarized the extent of knowledge by identifying that some of the approaches that worked included:

- Rehabilitation programs with particular characteristics
- Incapacitating offenders who commit crime at high rates
- Some prison-based therapeutic programs
- Programs based on cognitive behavioral therapy approach
- Nonprison-based sex offender treatment programs
- Vocational education programs in prison or in other residential settings
- Multicomponent correctional industry programs
- Community employment programs

Mackenzie also identified approaches that had been consistently shown not to work in reducing reoffending. These included specific deterrence programs, interventions based solely on control or surveillance, and boot camps and other wilderness programs. Counseling approaches that were vague and unstructured also had no discernible effect on recidivism rates. This vein of research continues with increasingly detailed knowledge being produced regarding what is effective in working with offenders. In the UK, the Probation Studies Unit of the Centre for Criminological Research at the University of Oxford had the stated goal of carrying out research into the effectiveness of various interventions, and they emphasized the need for well-designed studies to evaluate accredited programs (Roberts, 2004). In Australia, the New South Wales Bureau of Crime Statistics and Research (BOCSAR) is the official source of crime statistics for the state but also evaluates initiatives designed to reduce crime and reoffending (BOCSAR, 2013).

The focus of criminological attention on, largely quantitative, studies to determine the effectiveness of particular interventions on changing offender behavior has been subject to challenge and criticism within criminology. Feeley and Simon (1992) identified a new penology with a focus on actuarial and efficient and effective processes that could lower our expectations of the system and become detached from traditional concerns of rehabilitation or punishment. Garland (2001: 19) went further in describing the "all pervasive managerialism" that affected all aspects of criminal justice and led to a social way of reasoning being replaced by an economic way of reasoning. Cohen's (1985) concerns were that an applied criminology could be merely technicist and that measures introduced ostensibly to help and support an offender could simply become another mechanism of control. If applied criminology is to be more than merely technicist or administrative, then it must address these concerns and there are a number of ways that this has been done. Applied criminology is also concerned with the rights of offenders and with their own self-narratives regarding how they desist from offending, and in supporting them to do this.

A simple focus on the effectiveness of programs in addressing offending behavior can lead to crime being considered as a natural disorder, analogous to illness, and can leave crucial questions unexamined. For example, a simple focus on the effectiveness of interventions can ignore the fact that crime, and thus offending behavior, is social constructed. It can also neglect questions of the differential representation of particular groups in the criminal justice system and the link of that representation to questions of social justice. Viewing rehabilitation as a right, regardless of the effectiveness of particular interventions, can help address this problem. Rehabilitative and therapeutic services as well as educational and employment support can be provided without a need to calculate their effectiveness (Rotman, 1986). Carlen (2013) has gone further, arguing that a focus on rehabilitation is a distraction from the injustices in society and in the criminal justice system. She argues that we need an inclusive social justice that reduces inequality and promotes citizenship.

The increasing attention given to what is now known as desistance research and its focus on hearing from offenders regarding how they have moved away from offending has allowed criminological research and insights to become applied to work with offenders. Desistance research has early roots in the United States, particularly in the longitudinal life-course studies analyzed by Sampson and Laub (1993), which investigated how individuals became involved in offending and later came to cease offending behavior. They found that significant life events, such as getting married or finding employment, were correlated with desisting from offending. More recently, primarily in the UK, research and scholarship (see, for example, Maruna, 2001; Farrall and Calverley, 2006; McNeill, 2006) has built on and developed this research to create a desistance paradigm. The desistance paradigm emphasizes the involvement of the offender in his own progress toward desistance and the need to work through partnership, collaboration, negotiation, and an emphasis on strengths. Desistance is an active process, involving the building of social capital and the support of criminal justice practitioners; it is not simply a program that can be imposed on an individual to change their thinking. Crucially, what makes desistance research work in applied criminology is its explicit drawing of links to practice and its desire to provide a framework for both practitioners and policy makers (see McNeill, 2006; Farrall and Calverley, 2006).

A further approach to the application of criminology that avoids the simply technicist use of programmed interventions and that considers wider social justice and relational issues is restorative justice. Restorative justice will be discussed in the next section, within the context of how criminology can be applied to respond to victims of crime.

What Is to Be Done on Behalf of the Victims of Crime?

Criminology, and specifically the subdiscipline of victimology, has had a particular influence in the increased importance given to the needs of victims of crime in the criminal justice system. By the end of the 1970s, "many diverse forces had

converged to draw attention to the neglected role and importance of the victim in the justice system" (Strang, 2001: 72). These forces, from within and outside criminology, included (1) the rise of the feminist movement, which highlighted important issues around particular 'hidden' crimes including rape, sexual harassment, domestic violence, and child abuse; (2) efforts to establish children's rights, which increased acknowledgment that children were particularly vulnerable to victimization; (3) the introduction of victimization surveys, which showed that crime was unreported and grossly underestimated, thus highlighting the difficulties and distrust of the justice system felt by many crime victims; (4) the rise of victim compensation initiated; and finally (5) the introduction of legal and social reforms aimed at protecting and helping crime victims (see Goodey, 2004; Spalek, 2006 for a more detailed overview).

As these developments in the victim movement progressed during the 1980s, the rise of consumerism resulted in agencies being directed to care about the lay people using their "services" (Mawby and Walklate, 1994: 81; Simmonds, 2009). Until then, responding to victims involved providing degrees of compensation for physical injury, including medical services and income maintenance or cash benefits, but ignored those needs that arose as a result of mental or emotional harm (Webster, 1994). Initiatives were subsequently devised to provide a service to victim 'consumers,' victim advocacy groups enjoyed a more significant status, and 'service delivery' targets were used to monitor whether or not the structural and systematic problems encountered by victims were being addressed.

While the 'victim movement' and rise of consumerism have certainly marked an important change within criminal justice, the extent to which this can be said to have improved the plight of victims is still subject to considerable debate. The work of two critical scholars may be drawn on here to illustrate the point further. Nils Christie, a Norwegian criminologist, has substantially shaped how we think about who victims are and how they are treated by the criminal justice system. In 1977, Christie suggested that victims had their 'conflict' stolen by the criminal justice system, and in 1986 he argued that not all individuals are able to acquire legitimate victim status – the less 'ideal' a victim was the less 'justice' they received from the criminal justice process.

Later, Robert Elias (1993) contended that victims are often manipulated by governments to achieve punitive aims. This reality can leave the victim feeling bewildered in which justice is equated with severe sentencing as opposed to tangible outcomes for their suffering or losses. Elias (1990) went so far as to say that the victim movement in the United States could no longer be classified as a social movement at all, so completely had it been corrupted by right-wing political forces. However, this cooption can take other forms as well. Spalek (2006), for example, draws attention to how Victim Support in England and Wales has increasingly been seen as an adjunct to the formal justice system because of its success in securing a place at the center of government policy, casting other victims' groups such as rape crisis centers to the margins.

To further illustrate some of these practices, two important developments will now be reviewed: restorative justice, and the legal provisions, which cover the treatment of victims and victim participation within the criminal justice system.

Restorative Justice

Although the recent origins of restorative justice are widely contested (Clamp, 2014), most agree that the inherent failings of criminal justice created an impetus for alternative models to be devised. The emergence of restorative justice around the same time as the apparent 'demise' of the rehabilitative ideal (or the etiological and penal crises) is perhaps unsurprising as it mirrors objections to state monopoly; questions the role of the professional; and seeks to 'rebalance' responses to crime so that the views of the victim, the offender, and the wider community are taken into consideration. As such, it departs from current trends of 'punitive populism' and 'crime control' outlined in the previous sections in preferring humanitarian notions of restoration and reintegration.

Perhaps, the most significant theorist in this area is John Braithwaite who put forward the idea of reintegrative shaming, whereby the actions of the offender are denounced, but not the offender (Braithwaite, 1989). During the process, the offender is encouraged to acknowledge wrongdoing and make amends for his or her actions by responding to the harm caused to the victim, "thus demonstrating that he or she remains part of the law-abiding community and recognises its norms of acceptable behaviour" (Roche, 2003: 29). Reintegration not only places a requirement on the offender, but also on his/her family and other agencies in supporting the offender to overcome the underlying causes of the offending, which may stem from a variety of practical, emotional, and/or psychological need. This work, from Braithwaite and others, is one of the strongest recent examples of criminological insights being applied in practice.

Experimentation with processes that provide both victims and offenders with an active role in the resolution of their offences can be traced back to victim and offender reconciliation programs that originated in Kitchener, Ontario in the late 1970s (Zehr, 1990; Galaway and Hudson, 1996). Until recently, restorative justice has, for the most part, operated on the margins of the criminal justice system offering no real challenge to the dominant law and order ideology that prevails in many Western societies (Garland, 2001). It was not until the 1980s that the increased status of both the 'victim' and the 'community' contributed to a reconsideration of the role of the state in the resolution of offences (Van Ness, 1996; Albrecht, 1999; Zauberman, 2000; Zedner, 2002). At this point, the restorative justice experiment extended to the reform of youth justice systems on the basis of restorative justice processes and principles such as in New Zealand, Northern Ireland, and South Africa (see Clamp, 2008; O'Mahony et al., 2012), experimentation by the police (see Bazemore and Griffiths, 2003; Moore and Forsythe, 1995; Paterson and Clamp, 2012), and various communities (see Clamp and Paterson, 2011).

Adversarial approaches in criminal justice are often perceived as a zero-sum game between victims and offenders; thus restorative processes are increasingly vulnerable to cooption by the system. Restorative justice is susceptible to degenerating into a shaming ceremony in which wrongdoers are not reintegrated, but stigmatized and humiliated and where victims

are used as pawns to bring about change in the offender (McCold, 2002). Restorative justice can also have a tendency to endorse similar stereotypical notions of victimhood as the traditional criminal justice system (Walklate, 2005; Young, 2002). It is an alternative to formal justice, yet relies on established legal definitions of victims and victimization (Pavlich, 2005).

Developments in Victim Policy

International instruments have had considerable influence on the treatment and position of victims within the criminal justice process and the United Nations Declaration of Basic Principles of Justice for Victims of Crime and Abuse of Power (1985) is the most influential of these. The Declaration is not legally binding but can be used as a 'benchmark' to measure domestic policy progress (Van Dijk, 1989: 12), and its principles have become staples of policy discussion. These include access to justice, provision of information, fair treatment, and assistance in both formal and/or informal procedures. This has provided the impetus for a worldwide trend of designing and implementing victim rights charters, serving as official acknowledgment that victims have been marginalized and adversely treated by criminal justice agencies leading to secondary victimization (Spalek, 2006). The introduction of charters is a positive step for victims, but the use of the phrase 'victims' rights' can unduly raise expectations that victims are being empowered in some significant way (Fenwick, 1995).

Victims' rights legislation can communicate the services that victims can expect to receive from agencies of the criminal justice system (Spalek, 2006; Wolhuter et al., 2009) thus encouraging victims to think of themselves as individual consumers (Bennett, 2007). Such an approach reduces the potential for significant systemic change to occur so when victims are unhappy with the service that they receive, they are only entitled to make complaints – there is no mechanism through which they can enforce their rights. Changes in policy and practice that have been implemented across agencies of the criminal justice system under the guise of development of a 'victim perspective' or 'victim rights' have not necessarily led to significant improvements for victims (Spalek, 2006).

Promoting victims' rights might lead to giving victims a more active role in the criminal justice system such as by participating in prosecution or sentencing decisions. Many countries have now introduced victim impact statements, allowing victims to explain the impact of the crime on them. Proponents of this approach argue that victim involvement can increase prosecution efficiency, improve sentencing effectiveness, and increase victim satisfaction (McLeod, 1986; Kelly, 1987; Erez, 1990). However, critics are wary of the use of victim impact statements to legitimize a punitive stance against offenders (Ashworth, 1998) and have highlighted that the process can create unachievable expectations among crime victims regarding their influence over sentencing decisions (Fattah, 1986).

In a similar way as discussed previously with regard to offenders, applied criminology has been able to claim an influence over changes in approaches to victims in the criminal justice system in the recent decades, while also maintaining a critical stance over the meaning and consequences of some of these changes.

Conclusion

Applied criminology is a term now in widespread use in program titles, conference programs, and names of research centers, and the terminology sits alongside the applied iteration of other disciplines such as applied sociology or applied forensic science. The use of the term 'applied criminology,' however, has neither been accompanied by concerted attempts to define the term, nor are there leading scholars who prominently declare themselves as applied criminologists. It is perhaps due to the nature of the criminological discipline that the boundaries around applied criminology are so unclear; in a sense all criminology is practical and applied, just as all criminology is reflective and theoretical.

This article has outlined how criminology has been applied to the problem of what to do about crime, to work with offenders, and to responding to the needs of victims. Punitive strategies remain popular with politicians and the public, but they have little impact on crime rates. Police practice is held to account both by criminological scholars and researchers and increasingly by contributions from criminology to police training. Research insights inform the nature of the work carried out with offenders and contribute both to the nature of the interventions and, more recently, to the way objectives are set and notions of success are framed. Work with victims is more prominent and better funded than it was a few decades ago. However, victims' emotions have been translated into individual need using the discourses of consumerism and active citizenship so, although they are acknowledged, victims' needs are framed and used according to the bureaucratic and political goals that prevail.

Criminologists are concerned about how their work is received by wider society and the weight given to their research findings and insights. Two recent attempts to conceptualize this relationship between criminology and the public provide assistance in determining the nature of applied criminology. Braithwaite (2011: 137) asks criminology scholars to be 'sparkers,' stimulating debate and providing ideas for the players in policy and practice. Loader and Sparks (2010: 124) suggest that the role of the criminologist in policy formation is that of the democratic underlaborer, promoting a better political and policy understanding of crime and the response to it. McNeill (2011) observed that such a role could also be played by criminology in relation to practice and, that, perhaps, is the place of applied criminology – to spark ideas and inform the practice of those who work within criminal justice, particularly in direct work with offenders and victims.

Applied Demography

Abstract

The field of demography can be divided into two general areas, basic or academic demography and applied demography. In this article, I differentiate the latter from the former and go on to discuss characteristics of applied demography in general as well as those found in the practice of applied demography in the private sector and in the public sector. Because demography generally uses population data gathered under the *De Jure* concept, the article also discusses the importance of *De Facto* population information to the private and public sectors. Professional recognition of applied demography and training are discussed. In addition to references for citations in the text, a set of suggested readings is provided.

Introduction

Population estimates and projections are the heart and soul of applied demography and people have been making them for a long time.[1] In 1741, for example, Johann Süssmilch made the first of several estimates of world population (Swanson and Stephan, 2004) and in 1755, Benjamin Franklin was publishing projections of the population of the world (Swanson and Stephan, 2004). It was not until the middle part of the twentieth century, however, that these efforts became institutionalized within the private and public sectors.

Since applied demography is part of the larger field of demography, it is useful to start by defining what demography is so that we can put the discussion of applied demography into the correct conceptual context. Demography can be defined as the study of population, typically focused on five aspects: (1) size, (2) geographic distribution, (3) composition, (4) the components of change (births, deaths, migration), and (5) the determinants and consequences of population change (Swanson and Stephan, 2004, p. 758).

As the preceding definition suggests, demographers share conceptual frameworks, methods, and data in common. For example, a demographer who specializes in studying the geographic distribution of populations typically deals with population size, composition, the components of population change, and the determinants and consequences of population change. As such, this demographer would be using conceptual frameworks, methods, and data that would be familiar to other demographers, regardless of their specialties.

In spite of the shared commonalities, the work done by demographers can be distinguished in several ways. A distinction of interest here is that between basic (academic) demography and applied demography. Basic demography is primarily concerned with solving endogenously defined problems by offering convincing explanations of demographic phenomena, while viewing time and resources as barriers to surmount in order to maximize precision and explanatory power (Swanson et al., 1996).

Applied demography is primarily concerned with solving exogenously defined problems by producing the information necessary to effect practical decision-making, while minimizing the time and resources needed to produce this information (Swanson et al., 1996). Because basic demographers are largely working on problems defined by demographers, they tend to look at both the determinants and consequences of population change. However, applied demographers tend to focus on the consequences of population change because they usually are involved in answering questions posed by nondemographers.

Both basic and applied demography can, themselves, also be subdivided into two subsets. Basic demography can be viewed as being composed of (1) formal demography and (2) population studies. Formal demography can be viewed as mathematics applied to human populations, while population studies can be viewed as the application of sociological concepts and methods to human populations. There is overlap between formal demography and population studies in terms of concepts, methods, and data, but the distinction, nonetheless, is useful.

Applied demography's two distinct subsets are private sector demography and public sector demography. Both use the same methods, some of which are unique to applied demography, but also include some of the methods found in formal demography and many of the methods found in population studies. Private and public sector demography both use a great deal of data generated in the public domain, but because private sector data are too costly or proprietary, little of its data is even known within public sector demography, much less used by it.

As presently practiced around the world, applied demography largely owes its present configuration to two major factors, largely initiated in the United States: (1) the need by government to have data to develop policies and implement them and (2) the need by business to have data to guide its investment, production, and marketing efforts.

Although governments have long used census data, it was the advent of US government policy-making under the administration of President Franklin Roosevelt in the 1930s that set the stage for the need for data beyond the census, which, in turn, kicked off the move by governments at all levels to generate and acquire data for policy and administrative needs, both within and outside the United States (Prewitt, 2013). The utility of low-cost, timely, and useful data being generated by the US government was quickly recognized by the private sector. The private sector demand for such data soon outpaced what could be provided by the government and by 1970, statistics became a commodity independent of government and a statistical services industry developed, an industry in which

'demographics' found itself playing a key role (Martins et al., 2011).

Applied Demography in the Private Sector

There are multiple aspects to the statistical services industry and while there are often less-than-clear-cut distinctions among them, several can be identified, including econometrics, database development and maintenance, survey research, and demographics. Broadly defined, the latter can cover a wide range of activities, including actuarial work, public health, and market demographics. Of interest to us here is market demographics, which makes up the lion's share of the 'demographics' found in the private sector.

There are three major components of private sector demography: (1) the aggregation of personal demographic characteristics by geographic areas such as postal zip codes, blocks, block groups, and client-defined areas; (2) psychographic profiles of individuals aggregated into 'lifestyle' segments; and (3) the aggregation of household characteristics by geographic areas.

The personal demographic characteristics component sprang directly from two factors: (1) the growing interest on the part of major corporations in market segmentation and targeted marketing, which emerged as mass marketing methods began to falter and (2) technology developed within the public sector that enabled the association of demographic characteristics with addresses. Although it came to prominence in the 1970s, following the public release of the first-ever electronic files for census data from the 1970 census, the origin of this component can be traced back to 1950, with the founding of Market Statistics, Inc. (Pentilla, 2005; Morrison and Smith, 2005; Russell, 1984).

The psychographic component also came to prominence in the 1970s, but its origin is found in a 1960 report, 'Consumer Values and Demands,' issued by the Stanford Research Institute (Mitchell, 1983). Ideas from the report ultimately emerged as the 'Values and American Lifestyles' (VALS) project. In 1978, a full-scale VALS project sponsored by 39 corporations (Mitchell, 1983) bore fruit in 1983 in the form of the book by Arnold Mitchell, *The Nine American Lifestyles*.

As the first two components matured, they started feeding into one another. However, even when supplemented by psychographic profiles, 'zip code' demographics could not cover all marketing needs. One of these needs was the ability to segment and target down to the level of the individual household. As was the case for the zip code and psychographic providers, this need led to the third component, 'household characteristics.' Like the other two components, its implementation also required a substantial leap forward in electronic data storage and manipulation.

The origins of the third component, 'household characteristics,' can be traced to precomputer times, but these attempts were very limited. However, these attempts led to the assembly of credit and other data on households held by private companies with the goal of having 100% coverage of all households in the United States. By the early 1970s, these privately held household records approached the same number of households counted in the 1970 US census and have not lost ground since.

To update their records, household providers still rely on credit reporting services, but their efforts have extended to many other sources of data, including purchase data, supermarket savings cards, white pages, telephone usage, surveys, sweepstakes and contest entries, medical records, dental records, insurance policies, financial records, property records, motor vehicle data, automatic number information, credit card transactions, phone records, credit records, product warranty cards, the sale of magazine and catalog subscriptions, customer loyalty cards – and the United States Postal Service (EPIC, n.d.; Tripod, n.d.; US Postal Service, 2011).

While there are only a few companies in the credit bureau business, there are many small companies in the business of selling customized estimates, projections, and other types of analyses. Many companies define their market areas by postal delivery areas and while some national statistical agencies (e.g., the US Census Bureau, Statistics Canada) provide census data for these pieces of geography, they do not routinely produce estimates and projections for them. This is one of the reasons for the existence of the substantial market demographics industry.

While the private sector provides characteristics of interest (e.g., age, race, sex, recent purchases, income), it still relies on data from the public sector. The US Postal Service, for example, is a major source of information on changes of address (EPIC, n.d.; Pitney Bowes, 2008). This is important in the United States, where around 45 million people (about 15%) of the population aged 1 year and over is estimated to have moved in the past year (US Census Bureau, 2009).

The information on changes in address is provided by the National Change of Address Service (NCOA), which is administered by the US Postal Service. Groups that subscribe to the NCOA can obtain updates when a current customer makes a permanent change of address request to the Postal Service. This is the one of the primary methods by which companies obtain individuals' addresses after they move. Businesses can purchase the updates for as little as $5 per 1000 names.

As the preceding suggests, the private sector statistics industry in the United States relies on the support of the public sector. While the US Postal Service provides the private sector with individual-level information in the form of address changes, the aggregated information provided by the US Census Bureau provides benchmarks against which the private sector data can be compared and adjusted if needed. For example, if a private data vendor finds that its estimate of median household income for a given area is less than that of the Census Bureau's estimate, the vendor can adjust its modeling and other processes to match it.

Applied Demography in the Public Sector

Although there is overlap, the origin of applied demography in the public sector precedes its establishment in the private sector. In 1943, the state of Washington established the Washington State Census Board, which in of itself was not new since many states had conducted their own census counts in the late-nineteenth and early twentieth centuries. However, the act (House Bill 72, Chapter 81, Revised Code of Washington) establishing the Board set the stage for the generation of annual

population estimates (something that was, in fact, new) rather than census counts as a way to equitably allocate funds to incorporated cities struggling under the impact of huge population increases resulting from the entrance of the United States into World War II in 1941. The Board immediately started producing estimates (Washington State Census Board, 1944) and the process of developing annual population estimates for incorporated towns was soon on the path to being institutionalized at the University of Washington under the direction of Professor Calvin F. Schmid, who was selected as one of the Board's initial members.

By the 1950s, the Washington State Census Board was not only producing annual population estimates of the state's incorporated towns, but also population and enrollment projections. The utility of these activities was not missed by other states (and Canadian provinces) and California, Oregon, Alberta, British Columbia, among other subnational governments started establishing their own demographic units. This process was greatly assisted by the fact that many of the graduate students who worked with the Washington State Census Board at the University of Washington had moved into positions in these adjoining areas after completing their degrees. The state of Washington ultimately absorbed the Census Board directly into state government and today its legacy lives on with the forecasting unit of the Office of Financial Management, which is the Governor's Budget Office.

By the late-1940s, the US Census Bureau also started producing annual estimates for states and other subnational areas and by 1950s, it was producing population projections on a regular basis. Since both the federal government and several states were producing population estimates for the same areas, it should not be surprising that in the early 1950s, an informal movement took hold that was aimed at coordinating these activities.

In 1966, the National Governor's Conference, in cooperation with the Council of State Governments, initiated and sponsored the 'First National Conference on Comparative Statistics,' held in Washington, DC. This conference gave national recognition to the increasing demand for subnational population estimates. Between 1967 and 1973, a group of Census Bureau and state employees charged with developing annual subnational population estimates, formalized the 'FSCPE,' the Federal-State Cooperative Program for Local Population Estimates (US Census Bureau, n.d.). Jumping off a task force formed within the FSCPE, a little more than 10 years later, a similar organization (The Federal-State Cooperative Program for Population Projections) was established to coordinate population projection efforts.

Although many states reduced or eliminated their demographic activities between the heyday of these activities in the 1970s and the severe economic recession of 2007–12, the original core states of Washington, Oregon, and California still have highly functional and well-respected demographic operations, as do the states of Alaska, New Mexico, Texas, and Florida, and the provinces of Alberta, British Columbia, and Ontario, among others.

Demographic activities in public sector also are found within sub-state governmental units. Typically, these are in the planning departments of large cities and regional organizations such as Metropolitan Planning Organizations (also known as Councils of Government). The regional organizations often run very sophisticated demographic operations. One notable example is the San Diego Association of Governments, which hosts an annual research conference for demographers working in these regional organizations.

De facto Population Estimates

By now, you may have realized that the discussion of both private and public sector activities has been in terms of the definition of population used by the US Census Bureau, namely, the *'de jure'* population. This is the idea that in a census everybody should be counted once, only once, and in the right place (Cork and Voss, 2006). It is based on place of 'usual residence.' However, important to both the private and public sectors is another definition, namely the *'de facto'* population. This is the idea that in a census you count everybody once, only once, but in the place where they are found at the time of the census (Swanson and Tayman, 2011). Examples of *de facto* populations are many. They include vacationers (of interest, for example, to the hotel owners in Cancun, the casino industry in Macao, and the Hawaii Visitors Bureau), migratory workers (of interest, for example, to health care, school, and other social service providers), and the people who work in the central business district of a large city each day, but leave it largely vacant in the evenings (of interest to the San Francisco City Planning Office, for example).

While estimates of *de facto* populations are of great interest, they are difficult to make in countries that use the *de jure* concept of residency for their census counts. In addition, they are also difficult to evaluate in these countries because there is no 'gold standard' against which to measure them in terms of validity and reliability (Swanson and Tayman, 2011).

Professional Recognition[2]

As you have read, by the end of the 1970s, applied demographers in the public sector had a history of interaction and were involved in formal organizations that facilitated the advancement of the field. The federal-state cooperative programs for population estimates and projections, respectively, were instrumental in this regard. Demographers in the private sector were more isolated from one another and their colleagues in the public sector. Partly, this was due to the proprietary nature of their work and partly to the slow pace of hiring demographers on the part of major companies.

One affiliation that was shared between applied demographers in the private sector and their colleagues in the public sector changed that isolation in the late-1970s. The organization was the Population Association of American (PAA), arguably the world's largest single professional association for demographers of all stripes.

Founded in the 1930s, the PAA was almost entirely made up of basic demographers until the 1960s, when applied demographers started showing up at its conferences. By 1975, Harry Rosenberg, who was moving from the University of North Carolina to the US Center for Health Statistics, wrote to the

then-president-elect, Sidney Goldstein, of PAA urging him to include a session in the 1976 conference on state and local demography. While the letter came too late to have a session on state and local demography, it resulted in the first of an annual set of 'breakfast meetings.' By 1977, a formal session on state and local demography was included in the PAA's annual conference, as was the case in 1978, which also saw the first appearance of the official PAA Committee on State and Local Demography.

With annual breakfast and regular sessions, the 'state and local demographers' were soon joined by their colleagues in the private sector and by the early 1980s, a Committee on Business Demography was spun-off by the Committee on State and Local Demography. The two committees then joined forces to launch the 'Applied Demography' newsletter under the auspices of the PAA. By 1993, the two separate committees merged to form the PAA's official Committee on Applied Demography, which continues to sponsor not only the annual breakfast, but also an evening reception and several sessions in each of the annual PAA conferences. In addition to about 125 members who specialize in estimates and projections, the PAA has around a 100 members who specialize in business or state and local demography.

A separate track to professional recognition was provided by the Southern Demographic Association (SDA), which from its founding in 1970 (as the Southern Demographic Interest Group) was focused on applied demography. This organization was initially sponsored by the Oak Ridge National Laboratory (located near Knoxville, Tennessee) and its associated universities. Contact was made between Oak Ridge and Professor Everett Lee at the University of Georgia in regard to developing current population estimates that could be used for emergency planning, especially the evacuation of people from large population centers in the event of nuclear war. Like the PAA, this group held an annual conference at which demographers congregated and it quickly attracted the interest of applied demographers located in or near the southern region of the United States. Over time, this regional organization has grown to include members from outside the southern region of the United States.

The SDA began publishing upon its founding and eventually acquired a journal, *Population Research and Policy Review*, which became a publication outlet for many applied demographers. In addition to its journal, the SDA sponsors the Walter E. Terrie award, which is given to the author(s) of the best paper on applied demography presented at its annual meeting. This is the only award given anywhere in the world specifically for a contribution to applied demography.

Perhaps, the apex of professional activity and recognition is found in the form of the biennial conference on applied demography, which is sponsored and hosted by the University of Texas, San Antonio every other January since 2008. This conference filled a 15-year hiatus that resulted when the applied demography conferences started at Bowling Green State University in 1986 were discontinued in the 1990s. Selected papers from this conference are published in a proceedings book by Springer, which is edited by faculty members in the Department of Demography and staff at the Texas State Demographic Center, both of which are housed within the University.

Training

Training in applied demography has both a formal education component and an on-the-job component. For the most part, applied demographers have a bachelor's degree in one of the social sciences, typically sociology and geography. Many universities offer courses in applied demography, but at the undergraduate level there are neither formal degrees nor concentrations offered.

At the graduate level, however, there are several programs in addition to many individual courses. The University of California Irvine offers a 1-year program in applied demography that leads to a Master's Degree. A similar program is offered by Florida State University, while The University of Texas, San Antonio offers a PhD in applied demography. An entrance requirement to this program is possession of a Master's degree, but it need not be in applied demography. The graduate programs typically include courses on data sources, geographic information systems, and methods for estimating and projecting populations. Information on the courses and other requirements of these programs can be found at the Web site of the universities where the programs are offered.

Summary

The development of applied demography has been driven by the interaction of several elements that have shaped the nature of certain streams of research in demography. The first is the rise in the use of the demographic perspective, data and methods in addressing business opportunities and problems. Encouraged in part by the need for small area data, many demographers more recently have focused their efforts on the improvement of techniques and technology needed to generate, display, and analyze small area data, both for the private and the public sectors. While the vast majority of demographic research focuses on the demography of geographic units, it is worthwhile to note that an interest in organizational demography and other nongeography-based applications has emerged in the last decade or so.

The development of data through estimation and projection (particularly for small areas) has and will continue to be affected by continued improvements in methods and technology. Although the focus here has been on applied demography in the United States, developments in methodology and technology transcend national boundaries. These developments will, in turn, influence both applied demography not only in the United States, but elsewhere.

End Notes

1. A population estimate is the calculation of a current or past population, typically based on symptomatic indicators of population change, while a population projection is the numerical outcome of a particular set of assumptions regarding future population trends (Swanson and Stephan, 2004). It is worthwhile to add here that there is a distinction usually made between the term 'projection' and the term 'forecast,' with the latter being defined as

a population projection deemed most accurate for the purpose of predicting future population (Swanson and Stephan, 2004).

It is also useful to note here that there are two distinct traditions in regard to population estimates: (1) demographic and (2) statistical – that is, the methods used by those who do sample surveys. Demographic methods are used to develop estimates of a total population as well as the ascribed characteristics – age, race, and sex – of a given population. Statistical methods typically employ sample surveys in order to estimate the achieved characteristics of a population – educational attainment, employment status, income, and martial status, for example. Among survey statisticians, the demographer's definition of an estimate is generally termed an 'indirect estimate' because unlike a sample survey, the data used to construct a demographic estimate are symptomatic indicators of population change (e.g., K-12 enrollment data, births, deaths) and do not directly represent the phenomenon of interest. Among demographers, however, the term 'indirect estimate' has a different meaning (Swanson and Stephan, 2004). Most national statistical agencies produce estimates using both traditions, demographic and statistical. With regard to population projections, the distinction between the demographic tradition and the statistical tradition is less pronounced, however.

2. The information about the PAA's Committee on Applied Demography is largely drawn from Voss (2005).

Applied Geography: A US Perspective

John W Frazier, SUNY, Binghamton, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Applied geography is client driven and user oriented, and emphasizes useful information. It can bridge the gap between university and nonuniversity settings. Applied geography has a long history of leadership by both academicians and practicing geographers in the government and private sectors. Some public and private institutions have woven the use of geography into their institutional fabric. American examples include the US Census Bureau, the American Geographical Society, and the Association of American Geographers. At the international level, the International Geographical Union has institutionalized applied geography in its core. Applied geography also has a notable history in the private sector, including in the business community. Geography's main teaching and research themes are expressed topically in applied geography's pursuit of problem resolution in specific human–environmental issues, site selection, and many other subfields of the discipline. Applied geography has a very bright future in the twenty-first century, especially with the increased public awareness of the field and the value of its knowledge base and geotechnologies.

Applied geography provides a user orientation and an effectuation plan that are different from those of curiosity-driven academic research (Frazier, 1982, 2004). Applied geography emphasizes the social relevance of geographic research. It is characterized by the value context placed on knowledge. A dialectic between academic and nonacademic (or applied) geography is reflected in the work of many famous geographers of the twentieth and twenty-first centuries and is institutionalized in public and private agencies. Many current problems require an applied geography approach.

Applied geography emphasizes the social relevance of geographic research that focuses on human–environment interactions, area study, movements, and spatial location problems. In general, the spatial distributions and patterns of physical and human landscapes are examined, as well as the processes that create them. These provide the basis for recommended actions for a client. Applied geography takes place within and outside of university settings and often bridges the gap between academic and nonuniversity perspectives.

Wellar (1998a) has referred to the difference between purely academic research and applied research as curiosity-driven vs client-driven research. Whether university or nonuniversity based, geography becomes applied when the researcher undertakes a problem for a client. While academic geographers' research is driven by their curiosity to understand patterns and processes, applied geographers perform research for a client with a 'real-world' problem. This results in an approach that differs markedly from an academic endeavor. The client can be a retailer in a capitalist economy; a group that receives unequal treatment from a capitalist or some other group and, therefore, would benefit from the empowerment that applied research findings may provide; or any other person or agency seeking or needing relief from a solution to a geographic problem.

The 'applied' approach provides a user orientation and an effectuation plan quite different from those of curiosity-driven academic research. The research results are also presented in different formats and used differently. Applied research results may be input into the design of a new product, may result in a strategy for delivering a new product, or may be a set of recommendations that inform decisions. Academic research pursued for curiosity typically results in the production of a book, monograph, or research article in a journal publication for the purpose of informing colleagues of findings, especially in terms of the contribution to existing theory. Applied geographers in vs out of the university often differ in their views of what applied geography is. Despite these differences, applied geography is united by emphasis on useful knowledge.

University-based applied geography is narrower in scope than is nonuniversity applied geography. The university presumes a theoretical and an empirical basis for applied research. Non-university-based applied geography occurs within business and government cultures, which often results in highly specialized roles for individuals applying geographic knowledge and skills in the solution of problems. The differences between the two workplaces shape research perspectives, define broader nonresearch obligations, and result in different perspectives. For example, in the university context, the researcher controls and participates in all aspects of research, leading most academics to define 'applied' as the research performed by the researcher for a client. Most academics also emphasize research over effectuation planning.

By contrast, in a nonuniversity setting, an applied geographer has a job description that indicates specific tasks and places the employee in a reporting hierarchy (Frazier, 1994). Individual responsibilities are tied to a 'client relationship' that is inherent to a production environment. The employment specializations of nonacademic geographers range from planner–technician to analyst, from a research scientist to director of operations, and from project director to executive (Frazier, 1994). In the nonacademic world, every cog in the wheel is crucial. In short, the very nature of the nonacademic world requires multiple stages in the creation of a product. An applied geographer may be performing research or implementing the research of others, doing none himself or herself, but contributing greatly to the process. Being directly

involved in all parts of the applied research process is not a prerequisite to doing applied geography outside academia.

What holds applied geography together is the value context placed on knowledge. The applied geography approach seeks useful knowledge that helps solve a specific problem for a specific client. Pacione (1999) describes examples of practical recommendations for policy that address the issue of ethical standards in applying science. Specifically, he used British and American examples that illustrate applied geographers taking antiestablishment, unpopular positions to implement research findings that would change existing urban policies.

The goals of applied geographic research differ from those of basic research but the boundary between the two can be fuzzy. The value of 'useful knowledge' helps clarify the differences between the two approaches.

Applied Geography: An Historical Context

Early Leaders by Example

A dialectic between academic and nonacademic geography is reflected in the work of many famous geographers in the early twentieth century. Perhaps the most frequently cited case of geography in action is the work of L. Dudley Stamp in the Land Utilization Survey of Great Britain. Stamp called for geography not only to use its methods and concepts to interpret the world but also to help forward the solution of some of the great world problems (as quoted in Frazier, 2008: p. 3). Stamp's work in the 'Survey' put geographic methods and concepts into action and provided a touchstone for their utility. The 'Survey' methods and findings were replicated by others and informed geographic theory and approach for decades, providing not only planning inputs but also research topics in academic geography.

In the United States, several geographers of national reputation converted their academic interest in human–environmental topics into government employment. Among them were Harlan Barrows, who between 1933 and 1941 worked on a variety of water resource projects, including the design of comprehensive development schemes on a regional basis (Colby and White, 1961). Even earlier, Carl O. Sauer, an architect of academic cultural–historical geography, played a leadership role in the Michigan Land Economic Survey. The frequently employed theme of 'human as agent' was applied in this land assessment and classification effort. Sauer applied well-established academic geographic concepts and methods in an applied research mode. He dealt directly with specific forms of 'destructive exploitation' and their specific impacts on the land. Further, his scheme included a model of potential future uses, including modifications that would realize better results. Sauer's efforts were utilized in land management planning and were also published in the academic literature (Sauer, 1919); they informed future action and future academic research. Sauer followed up on applied research by being involved in the implementation stages as an activist.

The most internationally respected expert on natural hazards is the late Gilbert F. White. He is another example of an academic geographer who served the nonacademic community for half a century. White's early concern for victims of flooding and other natural hazards led to applied work for the administration of Franklin D. Roosevelt and new policy. White established academic and nonacademic followings and his leadership resulted in the creation of The Center for Natural Hazards Studies at the University of Colorado, Boulder. White and his colleagues have used geographic concepts and methods to understand different types of natural hazards and find ways to mitigate their impacts on people. Stressing physical and human variability, White focused on improving the plight of human kind (White, 1974).

While the review of applied geography in this article does not aim to be comprehensive, it would be remiss to exclude the founder of business geography in the nonacademic world. In the 1930s, William Applebaum accepted a position with The Kroger Company. His introduction of basic geographic concepts and methods for analyzing market regions was highly successful and created a career path for others to follow. Initially, applied geographers focused on measurement techniques, market delimitation, and competitor analyses. However, Applebaum maintained a close relationship with a small group of academic geographers and hired new geography graduates. Slowly, applied business geographers expanded their roles to include location analyses, site selection, and the application of models. As a result of this dialectic relationship between Applebaum and, later, others from the business world with academics, a new subspecialty, business/marketing geography, emerged in the United States and new concepts and methods were exchanged between the two environments. In Europe, Ross L. Davies is an example of an academically based applied geographer who spent a career conducting research that guided understanding of retail structure and behavior and that has informed business decisions.

Institutionalizing Applied Geography: Some Examples

Geography has been incorporated into government and business at various levels and in various ways. At one level, geography is inherent in business decisions and has resulted in many firms hiring geographers as location and/or site analysts (Grosvenor Center for Geographic Education, 2012; Solem et al., 2013). Some have risen to managers and executives. At another level, however, agencies formalize geography through their missions and/or internal organizational structure. Three examples suffice.

The American Geographical Society (AGS): Useful Knowledge and Geography in Action

When writing the history of the American Geographical Society (AGS), J.K. Wright noted its earliest public purposes: "The advancement of geographical science and the promotion of business interest of a 'great maritime and commercial city' were the Society's two leading purposes" (Wright, 1952: p. 69). These were most often expressed in the society's early years through published research reports, including those resulting from Society-backed field expeditions. An early example, which also reflects another Society purpose, supporting religious causes was the appointment of the 'Committee on Syrian Exploration,' which was championed by a rabbi and, according to the Committee, would "lead to important discoveries and human development by reclaiming the

desert, creating self-sufficiency and linking the region to world trade" (Wright, 1952: pp. 39–40). This was in keeping with the Society's purposes and exemplifies its efforts to put geography into action, which would promote human welfare.

In attempting to institutionalize applied geography in society, the AGS provided important data useful to government and business decision making. This is obvious in a number of the Society's efforts. In its early years, statistics had been hailed as knowledge capable of eliminating 'the fogs of human ignorance and suffering' (Wright, 1952: p. 47). The Society attempted to influence census taking and even proposed a new federal tax system as its 'most ambitious attempt to influence government policy' (Wright, 1952: p. 50). The intended applied thrust of the AGS is perhaps best stated in the inaugural issue of its major journal, *Geographical Review*: "It is the essence of the modern ideal that knowledge is of value only when transformed into action that tends to realize the aspirations of humanity. It is precisely this view that the Society has always taken" (*Geographical Review*, 1916: pp. 1–20, as quoted by Wright, 1952: p. 195).

Other national and international roles by the Society and its members are well documented. Among the most prominent are Society activities associated with the Congressional Act that established the International Meridian Conference in Washington, DC, and the leadership role of Society Director, Isaiah Bowman, in 'The Inquiry' after World War I. This enterprise was headquartered at the AGS. At the Paris Peace Conference that followed, Bowman served in an executive capacity at the request of President Wilson.

Most recently, the AGS has undertaken work that mirrors its long-term mission of creating useful information for foreign lands. Under the leadership of President Jerome Dobson, the Society created the Bowman Expeditions in the early twenty-first century. One of these expeditions, to Mexico, he labeled as a 'modern incarnation' of that mission that extended the early twentieth century effort termed 'The Millionth Map of Hispanic American,' by which the entirety of Latin America was mapped at the scale of 1:1 000 000 (Dobson, 2009: p. 3). Useful information has remained a cornerstone of the Society.

Applied Geography in Government: The US Bureau of Census Geography Division

Perhaps no federal agency anywhere has been more influenced by the geographic perspective than the US Bureau of the Census. For more than a century, the value of geographic knowledge has been applied in the acquisition and reporting of data for the establishment and monitoring of national and state programs in Commerce, Agriculture, Housing and Urban Development, Health and Human Resources, Indian Affairs, Transportation, Energy, Defense and Central Intelligence Agency, and other federal agencies. Applied geographers have played important roles throughout the federal government in such activities. However, the Geography Division of the US Census has long been charged with very specific duties, including the delineation of meaningful statistical areas as well as the creation and/or implementation of methods for the capture, organization, and reporting of useful geographic knowledge for problem solving. Torrieri and Radcliffe (2006) noted the early work of Census Chief Geographer, Henry Gannett, who by 1890 led the development of area definitions and mapping techniques, and was largely responsible for a variety of population reports, including the 'Report of the Nation' (Torrieri and Radcliffe, 2006).

Over the next century, geography's role expanded and, by 1978, Chief Geographer, Jacob Silver, provided a summation of responsibilities that included the development of national geographic reference files and digital mapping techniques (Silver, 1978). The development of the Geographic Base File-Dual Independent Map Encoding system provided the basis for future census taking and choropleth mapping of the US Census in the 1970s. By the 1980s, its national database development continued with Topologically Integrated Geographic Encoding and Referencing (TIGER), a digital street network for the entire nation, that permitted compliance with the federal mandate that all future census maps be digital. By the close of the twentieth century, the Geography Division's TIGER system became the most widely used digital base file in the world. Geographers also played an important role in the creation and administration of the American Community Survey. The Division is planning new census techniques, area definitions, and portrayal methods for census data in the twenty-first century.

Applied Geography in the Missions of Its Largest Organizations

Two notable examples of Geography's largest organizations incorporating applied geography into their missions are the International Geographical Union (IGU) and the Association of American Geographers (AAG). The IGU has seven broad objectives, including the promotion of applied geography through its 'Applied Geography' Commission. Its members have created multiple means of broadening the understanding of applied contributions, such as the 2004 volume that offered a global perspective from many scholars involved in these pursuits (Bailly and Gibson, 2004).

One of the most striking efforts of the late twentieth and early twenty-first centuries are the efforts of the AAG, which has effectively linked geographic education with the increasing demand for those with geographic skills. Through a series of National Science Foundation grants entitled 'Enhancing Departments and Graduate Education,' the AAG reached out to public agencies and private sector firms to better understand their current use of geographers and their future needs. These efforts have increased the visibility and depth of applied geography at the annual meetings of the AAG, attracting significant representation from the employment sectors hiring geographers. AAG-supported publications have also emerged that benefit students, faculty, and employers, such as *Practicing Geography: Careers for Enhancing Society and Environment* (Solem et al., 2013). Although Geographic Information Science (GIS) has been a big consumer of academic geographic talents, it has become clear that the wider applicability of GIS exists in the employment arena. For example, in the United States, *CareerBuilder.com* and the nationally syndicated *Sunday Jobs* noted that geographers 'study the earth and land (and inhabitants) and examine political and cultural structures as they relate to geography.' It also noted that geographers are in 'the top 10 jobs with above average salaries' (Auerbach, 2012).

Themes in Applied Geography

Most subdisciplines of geography contain examples of applied geography. Examples include a concern for environmental processes and patterns that influence human development and well-being, such as the physical processes of erosion, sedimentation, and desertification. Human–environmental relationships take on many forms but prominent among them are natural hazards behaviors, climate change, and environmental degradation of all types. The applied regional approach, or area study, involves any effort to create or analyze geographic zones for the benefit of human welfare. The leadership role of census geography has already been reported, but others include the creation of planning regions by applied geographers to plan, administer, and monitor urban and environmental areas. Location principles are applied to a wide range of analyses but are probably best known in applications for site selection in business and government and for retail market analyses, including the internationally known Huff model (Huff, 1964).

Torrieri and Radcliffe identified seven general classes into which they believe most applied geography falls: (1) market/location analysis; (2) medical geography; (3) settlement classification and statistical geographic areas; (4) land use, environmental issues, and policy; (5) transportation planning and routing; (6) geography of crime; and (7) developmental tools and techniques for aiding geographic analysis (Torrieri and Radcliffe, 2006). They admit that these classes are not exhaustive. It is unlikely that any nomenclature will satisfy all applied geographers. However, such classifications are useful in understanding the wide range of applied geography that occurs internationally.

One contemporary example illustrates geography at work in the transportation and routing area. Barry Wellar, who worked for the Provincial government of Ontario before becoming a professor at the University of Ottawa, led a research team under contract with that government to develop a 'Walking Security Index.' This index was used to assist Canadian officials and citizens in assessing the safety of signalized intersections for pedestrians (Wellar, 1998b). After developing the necessary indices and examples for the government, Wellar and his colleagues presented their results in public meetings and through the media. The final report contained 17 intersection recommendations based on the research and interactions with the three clients, government officials, staff professionals, and citizens. It also contained implementation issues and strategies.

Future of Applied Geography

Several trends indicate a bright future for applied geography. As noted above, applied geography was institutionalized both inside and outside academia in important ways. One trend is its increasingly formal treatment as part of academic debates (Pacione, 1999). Further, the British journal, *Applied Geography*, created a publication forum for those interested in particular aspects of this approach. Finally, in America, the annual Applied Geography Conference can be considered an institution that has brought thousands of applied geographers together from business, government, and the university for nearly four decades.

The second trend in geography is the recent improvements in geographic education at all levels. Professional European Geography was founded in the nineteenth century at least in large part as a result of educational concerns. At the close of the twentieth century, concerns for geographical ignorance spawned a revolution in geographic education. In America, the generosity of the National Geographic Society and the labor of educators of the National Council for Geographic Education have contributed significantly to improving the quality of geographic teaching through Geographic Alliances, which bring together K-12 teachers and university faculty in all 50 states. If applied geographers can be viewed as the 'outputs' of geographic education, then children are the 'inputs' that are shaped and mentored at all levels of the educational process. This trend of improved geographic education to rid the world of geographical ignorance has contributed positively to a third trend, that of greater public awareness of the importance of geography and its value, not only in better appreciating and understanding our local and global environments but also in contributing to the solution of significant global (e.g., global warming), national (e.g., poverty and inequality), and local (e.g., environmental health) problems. The establishment of the Grosvenor Center for Geographic Education at the Texas State University and a PhD specialization there in geographic education illustrate the increasing importance of this topic. So, too, do the employment trends previously mentioned.

Another trend that has contributed to our ability to recognize and solve geographic problems and to institutionalizing geography in the public and private sectors is the creation of geographic-based automated technology. Geography is now inseparably linked to information systems via GIS. Many employers seek technical and analytical employees who can use this technology in problem solving. Among the other digital technologies often linked to GIS and, therefore, extended to applied geography, are remote sensing and global positioning systems. Both technologies frequently find their academic homes in geography departments and are requirements for undergraduate and graduate degrees. In short, technical skills are now often associated with applied geography and its practitioners because they acquire, portray, and analyze useful geographic knowledge for problem solving.

Finally, and perhaps most important, there is no shortage of pressing global, regional, and local problems that require an applied geography approach. Many have been mentioned here. As long as there are geographers willing to contribute to the solution of problems that are inherently geographic or have geographic dimensions, there will be applied geography. Where geography is put into action, applied geography occurs.

Abstract

The history of applied social research is reviewed. The social sciences generally are a product of the Enlightenment and most of the social sciences originated in applied concerns. Thus, in contrast to the conventional view that the basic science is developed first and then applied to solving certain problems, most of the social sciences developed in the opposite direction: in the effort to understand and solve various social problems (education, crime, poverty, pestilence), the pioneers of the social sciences developed the theories, concepts, and methods that came eventually to comprise the basic disciplines. The history of applied social research is, indeed, the history of the social sciences themselves.

At the most general level, our topic is the historical relationship between basic and applied social science. Many discussions of this relationship posit the development of the basic scientific discipline – its theories, concepts, methods, and corpus of findings – as the necessary first step, and then the application of those theories, methods, and findings to problems of direct practical importance as a derivative activity, as an inferior or at least much less glamorous second step. Our thesis is that the historical development of the social sciences tended to follow an exactly opposite pattern. The earliest social science was developed by practical people seeking solutions to the pressing social problems of their day. Most of the social sciences were applied enterprises long before they developed as 'basic' scientific disciplines.

Origins

The idea of 'social science' emerged during and immediately after the Enlightenment, as a way to provide answers to questions about how individuals and institutions would cope with modernization, industrialization, mass political participation, the end of aristocracy, secularization, the spread of capitalism, the growth of the natural sciences, and, more generally, the end of traditional society. The Enlightenment, Edward Shils says, "was antithetical to tradition" (1981: 325) – the very traditions which, then and now, are "conducive to an ordered life." Without substantive traditions, how would modern societies function? What new bases of order would emerge? What, if anything, would prevent 'a widely ramifying disorder?' Would social life even be possible?

Scholars who eventually came to be defined as the founders of the disciplines of sociology, psychology, economics, political science, and even geography, and anthropology were all searching for an explanation of the post-Enlightenment world. Capitalism, science, democracy, and secularization were busily creating a new social order in the late-seventeenth and eighteenth centuries. By the nineteenth century, the Enlightenment ideas of reason, individualism, and freedom had created a nascent social science whose object was both to explain and justify this new order.

Those now considered the founders of the various social science disciplines all lived and worked at approximately the same time in history. Max Weber (sociology, 1864–1920), William Wundt (psychology, 1832–1920), and Franz Boas (anthropology, 1858–1942) were all born within three decades of each other. Adam Smith, arguably the founder of modern economics, was a century earlier (1723–90); and ditto Alexander von Humboldt (1769–1859), arguably the founder of scientific geography. The social sciences as we know them today were 'birthed' in the tumultuous period between 1750 and 1900, a period that includes the American and French Revolutions, the emergence of socialism, the unifications of Germany and Italy, the eclipse of aristocracy and the spread of mass democracy, and the political uprisings of 1848 on the Continent. This period simultaneously saw a shift in the scientific climate, where previously accepted thoughts and observations were challenged and empirical evidence was demanded.

Our point is that the questions the founders first asked were practical questions addressed to what we now call applied concerns. These applied concerns are the foundation of these disciplines as we know them today. As Alfred Marshall says (specifically about economics but more generally about all the social sciences), these disciplines are the "study of mankind in the ordinary business of life" (Marshall, 2011[1920]). They were not created for the purpose of producing theory-laden ideas in an icy laboratory or comfortable ivory tower but rather lively, warm-blooded, practical ideas that would not only explain, but also improve upon the welfare of society and everyone in it (Byrne, 2011).

The Enlightenment and the massive social transformations that ensued were important to the development of the social sciences both historically and conceptually. The rise of democracy and mass political behavior invested individuals and their actions with a new significance – democracy implied that the rulers were no more important than the ruled. Understanding variability in the behavior of individuals and locating those behaviors within specific social and institutional contexts became the *leitmotif* of a new breed of intellectual – not the philosopher, not the natural historian, but rather the social scientist. A century later, disciplinary lines of differentiation emerged, but the earliest of this new breed of scholar had wide-ranging interests in what we would now recognize as psychology, history, economics, sociology – indeed, the entire gamut of contemporary social science disciplines.

If the behavior of individuals was now of interest, then so too were their well-being, political outlooks, their views on

economy and society, all of which became fodder for social–scientific explanations of everyday life. As Jeroen Jansz (2004: 29) explains, "Rather than brute imposition of social order or religiously inspired charity, social management became infused with notions of rational, scientific social planning." Social management, not social theory, was the initial basis for what became social science as we know it. The animating concerns were things like crime and how to reduce it, education and how to increase it, poverty and how it might be eliminated, and on through a very large list of practical, applied concerns. The challenge was a data-based understanding of the world as it was, not the development of some concrete, general, and unwavering social theory that appeared to govern the happenings of society. A general theory of how the social world works was eventually the outcome, but by no means the origins of the applied work and concerns of the real founders of the social science disciplines.

Our intention here is not to debunk the importance of the traditional founders in the development of their respective disciplines, but rather to point out the applied and practical concerns of many of them to highlight applied origins and demonstrate that what is now considered 'applied research' is the precondition to the development of these disciplines as we know them today. Mainly, we aim to encourage modern contributors to these disciplines to pay homage to their applied roots.

Sociology

Johan Goudsblom and Johan Heilbron (2015), this Encyclopedia, argue that "American sociology developed primarily on the basis of empirical research into current social problems. The main topics were the issues which were widely debated by politicians, religious leaders and social reformers: massive immigration, urbanization, industrialization, local communities, social (dis)integration, ethnic and race relations. Empirical studies proliferated, based either on statistical material or on actual fieldwork. By the 1920s the sociology department in Chicago, founded by Albion Small in 1893, had become the predominant center." And while American sociology is not quite the same as sociology in general, this is a useful observation with which to begin.

If one were to ask the typical graduate student in sociology to name the 'founders' of the discipline, most would respond almost instinctively: 'Marx, Weber, and Durkheim.' A few might add Comte or Spencer to the list. And yet a recent paper by one of us (Wright, 2009) was entitled, *The Founding Fathers of Sociology: Francis Galton, Adolphe Quetelet, and Charles Booth; Or: What Do People You Probably Never Heard of Have to Do with the Foundations of Sociology?* (From whence much of the following discussion is adapted.) How, if at all, can these conflicting visions be resolved?

The notion that sociology began as a theoretical discipline originating in the ideas of European scholars such as Max Weber or Emile Durkheim is mainly due to the American Talcott Parsons, whose *The Structure of Social Action* (1937) and *Social System* (1951) pretty well *defined* the history of the discipline as it was taught in graduate departments from the 1950s forward. The 1937 book was particularly influential and was dominated by exegeses on Weber, Marshall, Pareto, Freud, and Durkheim. A like view of the discipline is promulgated in Robert Nisbet's well-known *The Sociological Tradition*, first published in 1966. Both Parsons and later Nisbet described the theoretical discipline as though it were the discipline in its totality and thus downplayed what Anthony Oberschall calls *The Establishment of Empirical Sociology* (1972), which owes a great deal more to, say, Galton, Quetelet, and Booth than to Marx, Weber, and Durkheim.

Even were we to grant that sociology was somehow 'founded' by the Big Three, we would also need to grant that all of them were motivated by strongly applied concerns. Emile Durkheim (1858–1917), for example, is often credited with making sociology a 'science' by insisting that social facts can only be explained by other social facts, a proposition suggesting that the individual acquires characteristics from society and not the other way around, thus appearing to deny the very idea of the individual in a radical way. It is true that Durkheim's many scholarly works and his founding and editing of the first journal of sociology, *L'Année Sociologique*, helped establish sociology as an accepted social science. But as George Ritzer has pointed out, Durkheim was quite open about suggesting social reforms based on his observations of the dismal state of education and the effects of the division of labor on social solidarity (Ritzer, 2011: 103, 106). *Suicide* too was dominated by practical concerns. The concluding passage of the first chapter expressed Durkheim's aspirations for the work, to discover "the means that can be used to counteract [suicide]" (1951[1897]: 52).

Max Weber (1864–1920) was known to his contemporaries primarily as a historian and an economist. Today, we tend to think of Weber as an abstract thinker, a theoretician, but he was intimately engaged in practical affairs and German politics: for example, he was a member of the German delegation during the peace negotiations in Versailles and a member of the committee that drafted the Weimar Constitution that paved the way for Hitler's ascension to power a decade or so later. Paul Honigsheim's *The Unknown Max Weber* (2000) refers to Weber as a 'rural sociologist' and elsewhere as a 'historian of agricultural and rural life.' It is hard to quarrel with the conclusion that "Weber's applied sociology has been given short shrift" (Swatos et al., 1998), due largely to Parsons' myopic insistence that Weber was more important as a theorist than as a practicing hands-on social scientist.

As for the third of the Big Three, Karl Marx, little need be said beyond the inevitable quotation from the *Theses on Feuerbach*: "The philosophers have hitherto only interpreted the world in various ways. The point, however, is to change it" (1969[1845]).

Venerated as these historical figures are, just what aspects of their work survive in contemporary sociology? Marx probably remains the most influential of the batch, although Marxian sociological themes have fallen out of favor in recent years. No one writes about suicide without a tip of the hat to Durkheim, but do the *Rules of Sociological Method*, the *Elementary Forms of the Religious Life*, or even *The Division of Labor in Society* still inform much current sociological research or practice? Weber, of course, lives on in studies of bureaucracy and in studies of 'class, status, and power,' and his *Protestant Ethic and the Spirit of Capitalism* is a hardy perennial in undergraduate social theory classes, but beyond that, what?

Consider, in sharp contrast, Sir Francis Galton (1822–1911), a contemporary of Marx, Weber, and Durkheim. At various points in his career, he would have been described as an anthropologist, sociologist, explorer, geographer, meteorologist, geneticist, psychometrician, psychologist, criminologist, and statistician, among others. There is not a single reference to Galton in Nisbet's 350 ponderous pages and it appears that few sociologists have ever heard of him. And yet his intellectual contributions include the following:

- According to Karl Pearson, Galton invented the concept of statistical correlation (Pearson, 1914).
- Galton was the first to apply statistical methods to the study of human differences and the inheritance of intelligence.
- Galton introduced the use of questionnaires and surveys for collecting data on human communities, which he employed in his genealogical and biographical works and for anthropometric studies. In an important sense, he invented the modern survey questionnaire and other features of the modern survey.
- He coined the phrase 'nature versus nurture' and was the first person to study genetic inheritance versus environmental conditioning and socialization as determinants of human characteristics.
- He is also considered the founder of psychometrics (the science of measuring mental faculties and psychological and social–psychological properties).
- In the late-1860s, Galton conceived the concept of the standard deviation.
- Galton also invented ordinary least squares regression and the use of the regression line; he was also the first to describe and explain the common phenomenon of regression toward the mean.
- In the 1870s and 1880s, he pioneered the use of the normal distribution to fit histograms of actual tabulated data. He also discovered the properties of the bivariate normal distribution and its relationship to regression analysis.

It does not overstate to say that any current issue of the *American Sociological Review* (or, for that matter, the *American Political Science Review*, the *American Economic Review* – indeed, any current journal in any social science discipline published anywhere in the world!) would owe as large an intellectual and historical debt to the Galton *corpus* just summarized as it would owe the Big Three combined. Contemporary social science, as it is actually practiced, is inconceivable without reference to Galton's techniques, concepts, and statistical theories.

What motives drove Galton to this dizzying string of discoveries and breakthroughs? Clearly, the motives were practical, not theoretical. Galton's passion was the statistical study of variations in human ability. The fundamental observation that drove his scientific work was that some people possessed talent in great abundance, and others, barely at all. What accounts for that variation and could anything be done about it? A more practical concern is difficult to conjure! As James Newman (1956) put it in his monumental history of mathematics, Galton was "essentially a social reformer," "imbued with a strong sense of social responsibility and of mission" (p. 450).

Adolphe Quetelet (1796–1894) was another contemporary of the founders and one of the most influential social scientists of the nineteenth century. He expanded a field of investigation that he termed 'moral statistics,' a field originally identified as 'political arithmetic' by English economist and philosopher Sir William Petty in the late-seventeenth century. Like Galton, Quetelet was a pioneer in the use of statistical reasoning to study social phenomena and as such, he profoundly influenced the course of European and eventually American social science. It is of some significance that when Paul Lazarsfeld was given a named chair at Columbia in 1962, the name he chose was the Quetelet Professor of Social Science.

Quetelet is rarely mentioned in modern-day histories of the development of social science, but his efforts to apply probability theory and statistical analysis to data on crime, suicide, and anthropometry were pioneering efforts whose progeny include criminology in its contemporary quantitative form. Nisbet's history of sociology identifies Quetelet as one of the 'political arithmeticians' who "compiled quantities of social statistics, pointing to correlations or 'patterns,' and preening themselves on the quantitative exactitude of their handiwork." From this, one would never know that Quetelet was a venerated figure throughout the nineteenth century, among empirical researchers in Victorian England and on the Continent (Cole, 1972).

What Nisbet (2004) described as 'preening' was in fact a near-obsession with accurate measurements of human characteristics. Quetelet believed that if measurements were sufficiently accurate, then observed sample values could be used to infer properties of entire populations. He did not quite grasp our modern concept of statistical inference, but as can be plainly seen, he came very close. He applied these concepts to statistics on crime, mortality, weight, disease, intelligence, occupations, levels of education, religious affiliation, economics, and other phenomena. His emphasis on accuracy in measurement led him to devise many improvements in census taking and data gathering. In a pamphlet on crime issued in 1831, he intuited what we know today as the law of large numbers and also intuited the effects of increasing sample sizes on what we now call 'the standard error of the estimate.'

Like others, Quetelet's scientific work was motivated by a reformist vision. He was interested in crime because he wanted to end it; in mortality because he wanted to delay it; in education because he wanted to maximize it. To the extent that these scholars had an academic agenda, it was to demonstrate that a true science of society was indeed possible and to show what such a science would look like.

Also worthy of mention in this context are the various statistical societies in Britain and on the Continent that came into being in the mid-to-late nineteenth century (see Elesh, 1972) – the Manchester Statistical Society (1833), the Royal Statistical Society (1834) (founded, incidentally, by Quetelet), the International Statistics Congress (1853), and even the American Statistical Association (1839). As David Elesh notes, all of these societies were sponsoring or in many cases doing themselves applied social research work that today we easily recognize as precursors to empirical social science.

Finally, there is Charles Booth (1840–1916) who, like Galton, goes unmentioned in Nisbet's history. And yet "many people trace the origins of modern survey research to Charles Booth, who produced a landmark study titled *Life and Labor of the People of London*," published in 17 volumes (!) over the

period 1889–1903 (Groves et al., 2009: 4). If we accept the conventional idea that Booth's London surveys were the first 'true' sample surveys of the modern form, then we must again acknowledge the primary role of applied issues in the conception and maturation of the discipline. John Madge's (1962: 536) comments on Booth's work and on the 'social survey movement' that Booth initiated are insightful and worth quoting. 'The social survey movement,' he says, "… was generally concerned with the type of sociography needed to establish the incidence of social evils, primarily with poverty, with the purpose of arousing public opinion into taking practical measures to deal with such evils. One cannot disagree with the verdict … that the social survey is not concerned with evolving any comprehensive sociological theory."

American sociology was also rooted in applied concerns. The focus of the early Chicago School on applied, practical problems was quoted earlier in this article. Many people consider the Chicago School to be the original foundation of American sociology, but this overlooks the important sociological work on race undertaken in the Atlanta Sociological Laboratory under the direction of W.E.B. DuBois at the end of the nineteenth century. DuBois's *The Philadelphia Negro*, although routinely ignored for generations, was not only the first social scientific study of recently freed African-Americans, it was the first seriously scientific sociological study ever done in the United States (see Wright, 2012, for details).

Psychology

Psychology provides another example of how the reality of discipline development is different from textbook caricatures. In most accounts, the first recognizably modern psychologist was the German Wilhelm Wundt (1832–1920). Wundt was a professor, a scholar, when he first proposed that psychology should be seen as an independent discipline, separate from and not reducible to biology, physiology, or philosophy (Jansz, 2004). His version of psychology focused on consciousness, that is, on a person's subjective experiences of self, others, mind, and the world at large. He is notable within psychology for having founded the first experimental psychology laboratory, in Leipzig in 1879.

It is of some significance that the first line of research taken up in Wundt's laboratory concerned human reaction times, and was animated by very practical, applied concerns. The story goes that Wundt was inspired to study this topic when astronomers were having trouble in accurately measuring the passing of a star through the crosshairs of a telescope. The measured time was different for each observer, which was attributed to the incompetence of the assistants doing the measurements. Wundt's insight was that the variable was not incompetence but reaction times that differed for every observer. "The reaction time studies conducted during the first few years of Wundt's laboratory constitute the first historical example of a coherent research program, explicitly directed toward psychological issues and involving a number of interlocking studies" (Danziger, 1980a: 106).

Wundt maintained that experimental psychology could only measure sensory input and motor output and that the most interesting inner workings of the mind would remain the province of the armchair philosophers (Bolles, 1993). Although his achievements were cited often by his contemporaries, few of his theoretical concepts or empirical results survived his lifetime (Jansz, 2004: 32). As Kurt Danziger concludes, Wundt's "crucial contribution seems to fall in the area of methodology rather than in the area of substantive theoretical concepts or specific empirical discoveries" (1980b: 109). Aside from the original reaction time studies, Wundt's psychology could not be said to have been animated by strong practical concerns. His mixture of physiology, psychology, lab procedure, and philosophy of science would seem to mark him as a classical 'academic' psychologist. Yet one of Wundt's earliest students was the Philadelphia-born Lightner Witmer, who earned his PhD in psychology under Wundt in 1893. Witmer "was one of the first to recognize the need for a field that applied psychology to real life, as opposed to it remaining purely experimental" (Pernaski et al., 2013). He is also credited with establishing the first psychology clinic in the United States and is often cited as the founder of clinical psychology.

Witmer's clinic was not based on any particular 'theory' of mind or 'school of thought' in psychology; his practical psychology was based more or less exclusively on "investigating the mental development of schoolchildren using statistical and clinical methods" (Fancher and Rutherford, 2012). A key clinical innovation was his "training school for the treatment of children suffering from retardation or physical defects that interfered with school progress" (Fancher and Rutherford, 2012). In one famous case, Witmer observed that a child having academic difficulties could not see well and thus procured for this student a proper pair of glasses, whereupon the student's academic progress improved. There was no Jamesian epistemology, no theory of consciousness, involved in this 'practical psychology.' The boy could not see!

In addition to Wilhelm Wundt and his students, Sigmund Freud (1856–1939) is often cited as a 'founding father' of academic psychology. Like Wundt, Freud's background was in biological science (neurology) and early in his career as a physician, he conducted research on cerebral palsy, aphasia, and neuroanatomy. But Freud's interests rapidly transcended biological confines. It is well known that his interests in psychotherapy originated in his interactions with Josef Breuer (1842–1925) and Breuer's treatment of one 'Anna O' (real name: Bertha Pappenheim). Anna O suffered various psychosomatic symptoms whose origins were diagnosed as 'hysterical,' the treatment for which was making her recall past events. Whether the reported remission of symptoms was real and whether the remission was due to the recalling intervention remain matters of contention. What is not disputed is that Freud saw in this experience a method to treat a wide variety of psychiatric disorders, an insight from which psychoanalysis was born, and that his animating interest was in developing methods to treat mental disease (not to develop grand theories of the Unconscious, as many commentators would have it).

To the early American psychologists, the application of psychology to a wide variety of pressing social problems and issues was "As American as Apple Pie" (Goodwin, 2012). The range of applications of early American psychology was far reaching and sought to further the discipline while simultaneously serving humanity. Applications included mental testing, the use of psychology in business and industry, and the

use of psychology to address personal psychological problems (what eventually became clinical psychology).

Mental testing began as a way of identifying students who were 'behind' and aiding them in achieving better academic performance. The method, of course, was the modern intelligence quotient test developed by Alfred Binet (1857–1911) and his colleague Theodore Simon (Goodwin, 2012). Binet and Simon believed that if one could identify low performing, academically disabled students reliably, these students could be sent away to receive the attention they needed to catch up (in this case to the Vineland Training Institute in New Jersey, a group home for 'feebleminded' children) (Goodwin, 2012). Lewis Terman expanded on the Binet–Simon test in 1916 with the Stanford-Binet intelligence test which, after many revisions, is still used today. Robert Yerkes (1876–1956) expanded on Terman's work by developing the first group tests given to army soldiers to determine whether soldiers were in the right positions or which soldiers might make good officers. Later in the 1920s, Yerkes and Terman united to create the first group tests in schools, the Scholastic Aptitude Test, which, also after many revisions, is still in use today.

A large group of psychologists who had been initially trained as experimentalists saw that their expertise had potential practical (and profitable) application when utilized to solve recurring problems in the private sector. Hugo Munsterberg (1863–1916) was the first to explore what is today called forensic psychology and later what is now known as industrial and organizational psychology (both with their own sections in this Encyclopedia). Munsterberg saw the critical importance of psychology in selecting juries (Munsterberg, 1908) as well as the benefits of understanding how psychology could affect consumer patterns (Munsterberg, 1913). Walter Dill Scott (1869–1955) also investigated the role of psychology in industry and business. He was commissioned by an advertising agency to research the psychology of advertising; today, psychological research is an integral and significant part of the advertising and marketing industry (Scott, 1903).

In the United States, clinical psychology began as a means to treat students with academic problems. Lightner Witmer, as discussed earlier, set up a section of his lab for the treatment of these children and created the term clinical psychology (this field too has its own section in this Encyclopedia). A key impetus to the growth of clinical psychology was the aftermath of World War II, when nearly 60% of returning veterans appeared to suffer from some type of mental illness. Since then, the application of psychology to solve practical problems has continued to grow within the discipline (Jansz, 2004). A shift from a primarily academic and laboratory-based endeavor to a social enterprise, accepting of its unavoidable existence within the practical context of modern society, has meant psychology is increasingly paying tribute to its roots in applied social science.

Economics

As with all the other social sciences, strands of economic thinking go back to the ancient Greeks; important precursors from the Enlightenment era include the utilitarians and the social contract thinkers (Bentham, Locke, Hume). But most economic historians trace the origin of the modern discipline to Adam Smith and his *Inquiry into the Nature and Causes of the Wealth of Nations* (usually rendered as *The Wealth of Nations*). The question Smith raised was what accounted for the obvious (even then) variation in national wealth. Some nations, that is, were obviously very wealthy; others were not. How could these differences be explained? The mercantilists argued that the basis of national wealth inhered in the accumulation of precious metals (mainly silver and gold); Smith eventually argued himself to the position that the true difference lay in the productivity of labor, but that became practically a footnote in the work as a whole. What Smith produced in the process of puzzling over this question was nothing less than a paradigm for the understanding of the political economy of capitalism. This, surely, is the foundational basis for all of modern economics.

Today's economists are criticized by some as maintaining relatively little interest in the history of their discipline outside obligatory courses in the history of economic thought. In economics, 'history' is but "a time series embedded within a set of data" (Kates, 2013: 17), not events and ideas to go back to, analyze, and learn from. Students of economics are shown the classical theories then "told not to go there" (Kates, 2013: 2). So, as with many of the social and behavioral sciences, the true origins of the discipline of economics have given way to texts and articles 'no more than 20 years old' that contain, at best, a caricature of the discipline's foundation and development (Kates, 2013: 1).

Contemporary economists often study the economic implications of various policy changes in order to frame and concretize policy decisions. This directly implies that a crucial charge of economics today is to solve real-world problems (Kates, 2013). Take, for example, the economic controversies surrounding proposed increases in the minimum wage, changes in immigration policy, educational policy, or welfare policies of all sorts – indeed, about nearly any policy being considered at the national level anywhere in the world. This is reminiscent of David Colander's (1992) lament that "applied economics" is "what most economists do" (p. 197).

The phrase 'applied economics' was first used by the British economist John Neville Keynes, father of John Maynard Keynes, arguably the most influential economist of the twentieth century. Keynes drew a distinction between the 'science of economics,' by which he meant formal economic theory that could be developed deductively, by reasoning from first principles without the pesky interference of economic facts; and the 'art of economics,' using the scientific laws and principles of the discipline to solve practical, applied problems. The "art of economics" was labeled "applied economics" (Colander, 1992).

Today, most of economics inside the academy and all of economics outside of it is "applied economics" in Keynes' sense. Many university departments of economics will have economic theorists on the faculty and most of the Nobel Prizes in economics are for theoretical breakthroughs. But most economists are economists *of* something: labor force economists, demographic economists, agricultural economists, environmental economists, education economists, and on through a long list that is more or less isomorphic with the undergraduate economics curriculum in most universities.

A key tension in modern economics is between the elegance of formal economic theory and the grubbiness of modern economic realities. As David Byrne (2011) explains, many foundational economic principles have failed to predict or explain much of anything in the real world, due largely to unrealistic assumptions required to maintain *ceteris paribus* conditions within models, which can never be the case in reality (Byrne, 2011: 182). Formal theory demands these assumptions; the real world regularly defeats them. A key element in the economic controversy over increasing the minimum wage was simply whether neoclassical price theory could be successfully applied to wages and employment. This was much more important to the economists than to the economy (Leonard, 2000).

Political Science

Founders of political science are often said to include Thomas Hobbes, John Locke, and Niccolo Machiavelli, among others. Later Herbert Baxter Adams (1850–1901), John Burgess (1844–1931), William Dunning (1857–1922), and Albert Bushnell Hart (1854–1943) established the discipline in the United States during the late-nineteenth century and early twentieth centuries. Adams founded the "Johns Hopkins Studies in Historical and Political Science" in 1883, one of the first journals devoted specifically to political science. Burgess found *Political Science Quarterly* at Columbia in 1886. And Dunning and Bushnell both contributed greatly to the Reconstructionist literature after the American Civil War.

Despite the European precursors (Hobbes, Machiavelli), political science is often said to be an American invention. It was the Progressive Era in the United States (1890s–1920s) and the concerns of that era gave rise to a discipline dedicated to the application of its knowledge, concepts, and techniques to address current political and societal issues. Raymond Seidelman and Edward Harpham (1985) propose that the persons most directly involved in taking the discipline in an applied direction included Woodrow Wilson (1856–1924), Charles A. Beard (1874–1948), Charles Merriam (1874–1953), and Harold Lasswell (1902–78). In Seidelman and Harpham's (1985) account, Wilson is rendered as the grandfather of the discipline and Beard, Merriam, and Lasswell as forgotten uncles.

Even Woodrow Wilson's work as a political scientist prior to his Presidential win in 1912 included advocating for the application of the science to aid the government in knowing what they could do better and how they could work more efficiently. Wilson began his piece *The Study of Public Administration* (1887) by pointing out (in the first sentence) that the only sciences that get studied are those sciences that are necessary in a society (i.e., sciences with some *application*). And in the first sentence of his other major work, *Constitutional Government in the United States* (1908), Wilson pointed out that his goal throughout the piece was to explore the US Constitutional system "with an eye to practice, not to theory" (p. 1).

Charles E. Merriam was a builder of the modern discipline of political science and his influence can be seen in essentially every facet of political science as it is practiced today. He is best known academically as the founder of value-free behavioralism, which aimed to understand, free of ideological lenses, the psychological and social factors that shaped mass political behavior. His more pronounced influence on students and professionals of political science came from his ability to persuade a generation of political scientists of the importance of understanding the reasons behind specific political behaviors and how the understanding of those underlying reasons could be the bridge between academic political science and the workings of the federal government. This was the behavioralism revolution that lives on today within the discipline.

Merriam, along with many others, sensed a crisis within America's democracy at the beginning of the twentieth century and dedicated much of his science to finding a solution. He was obsessed by the possibly deleterious effects of rapid technological change on politics and society and wanted to ensure that scientific knowledge was being produced in a way that could be useful to the masses as well as the federal government. Along with many others, he was fascinated by the apparent contradiction between Americans' zealous embrace of ingenuity, innovation, all that was modern, versus an often parochial, even antique political culture. His solution, rendered in modern terms, was to integrate science, including social science, in the political culture *and* in the political process. Science, he felt, would need to become "a non-revolutionary extension of democratic culture in America" (Barrow, 2000: 114).

It was not until Roosevelt's presidency began in 1933 that Merriam saw the uniting of academic political science study and its application. The onset of the Great Depression meant Washington was more interested in the advice of social scientists than ever before. As Seidelman and Harpham describe, applied political science was "vindicated" (Barrow, 2000: 126), as academics secured a place at the public policy table. Roosevelt mirrored Merriam's affinity for practicality and for an experimental approach to democracy.

Charles A. Beard is considered more of an historian than a political scientist by present-day scholars, but he played a major role in the development of the discipline (Barrow, 2000). Beard's work was popular among intellectuals and laymen alike. He felt that one of the most important questions to be asked of the modern (late-nineteenth century) political system was who would conduct the industrial and economic planning for the country. He founded the Rand School of Social Science in 1906 in order to train officials, party organizers, labor journalists, and others in socialist theory and applied social science in order to give them the academic edge he thought they needed to be successful.

Other Disciplines

Both space and expertise limit the attention we are able to give to the applied origins of the other social sciences: of geography, anthropology, and the like, not to mention all the subdisciplines: gerontology, criminology, demography, and all the rest. Anthropology, as all the social sciences, can trace its roots to the ancients, but modern anthropology greatly expanded as a direct result of European colonialism, the contact of the colonizing powers with indigenous populations, and the obvious administrative needs of the colonial and imperial powers to understand these indigenous populations, their languages, customs, institutions, and cultures. Anthropology and related sciences

sprang into existence to satisfy these managerial needs to study scientifically the cultures of colonized people – a source of some embarrassment to modern-day anthropology.

Geography is arguably the oldest of the social sciences, since the need to understand and record where things are is prehistoric. But the evolution of geography into a recognized academic discipline took place, again, in the post-Enlightenment era, during the late-eighteenth and nineteenth centuries. Alexander von Humboldt is usually considered the father of geography as an academic and scientific discipline. Humbodlt's famous survey of the geography of Latin America (1817) laid the foundation for the science of physical geography and to some extent meteorology also. He was among the first to realize that latitude provided a means to compare climatic conditions in different countries and to measure the decline in temperature with altitude, and he intuited the geophysical causes of tropical storms. He is also the progenitor of the idea, now common in geographical circles, that the proper domain of geography is at the intersection of geology, biology, and meteorology, that these intersections determined where plants grew and thus where animals would concentrate; from this, the spatial ecology of the human species could be properly inferred.

Today, the geographers have expanded their rightful domain to include the spatial aspect of all social activity and structure; thus, there is a geography of knowledge, crime, disability, even finance and children, among many, many others, all with corresponding entries elsewhere in this Encyclopedia. The situation in geography is thus reminiscent of that in modern economics: a few core techniques and basic principles as the 'science of geography' and an enormous range of applied work that defines the discipline's 'art.'

Conclusion

The history of 'applied social science' is indeed the history of the social sciences themselves. There can be no finer a conclusion to this article than a passage from an article by the sociologist Alvin W. Gouldner (1920–80) on "Explorations in Applied Social Science" (1989[1956]: 27)

> There seems to be no close correlation, therefore, between the development of generalizations by the pure disciplines and the multiplication of opportunities for, and varieties of, applied sociology. The applied sciences cannot be fruitfully regarded as springing Athena-like from the furrowed brow of the pure disciplines. Any metaphor which conceives of applied social science as the offspring, and of the basic disciplines as parents, is misleading. It obscures the point that the applied sciences often contribute as much to pure science as they receive from it.

Abstract

The term 'applied sociology' refers to a diverse group of practitioners all using sociology to 'understand, intervene, or enhance human social life'. Many different approaches to sociological application exist. We use the term 'sociological practice' or 'practitioner' to inclusively refer to applied, clinical, and public sociologists, as well as those who identify more with methods used across the social sciences: community-based researchers, participatory-action researchers, and translational researchers. With their work, all of these sociologists intend to impact groups of people in the present day. They primarily differ in the clients with whom they work and their level of engagement in implementing the action steps of a project.

Introduction

As Jim Wright points out (2009), applied sociology is and has been the foundation of basic sociology since the discipline began some 200 years ago. In the United States, Lester F. Ward called for applied sociology in his 1906 address to the first gathering of the American Sociological Association (then Society): "…sociology, established as a pure science, is now entering upon its applied stage, which is the great practical object for which it exists." The tradition of applied sociology grew with the Chicago School's focus on the social problems of that era and with the work of W.E.B. Dubois and Lewis (1999). (For a more direct discussion of this evolution, see Miller Iutcovich (1997).) Social scientists applied sociology by evaluating the impact of the New Deal programs during the Great Depression and the impact of World War II on soldiers and families (Hooks, 1983). Today, applied sociology is a diverse field, encompassing clinical sociology, public sociology, community-based research, participatory-action research, and translational research. (Some scientists refer to this method as translation, others as translational.)

In light of this variety, we see the topic of 'what is applied sociology' as an ongoing conversation. Members of the applied community routinely discuss this in a variety of venues, including the Association of Applied and Clinical Sociology and the Commission on Accreditation Programs in Applied and Clinical Sociology, as well as the American Sociological Association's section on Sociological Practice and Public Sociology. Members of sister organizations often apply sociology too, including the Association for Humanist Sociology, Sociologists without Borders, Society for the Study of Social Problems, and the International Sociological Association, among others. With all these organizations and all these types of sociologists, there is much we could discuss here. We offer a few key points.

A Working Definition

Applied sociology is using the sociological tools to "understand, intervene, or enhance human social life" (Steele and Price, 2004: p. 4). People apply sociology when they use sociological methods, theories, concepts, or perspectives (tools) to address a social problem or issue (Steele and Price, 2008). Lots of social scientists 'use' sociological tools in their teaching or in their research. But only a subset uses those tools to plan or engage in direct, concurrent social intervention or enhancement. We generally refer to those that do as applied sociologists. Many different approaches to sociological application exist. We use the term 'sociological practice' or 'practitioner' to inclusively refer to applied, clinical, and public sociologists, as well as those who identify more with methodology used across the social sciences: community-based researchers, participatory-action researchers, and translational researchers (Weinstein and Goldman Schuyler, 2008).

Drawing on the works of David Cooper (2011) and Price et al. (2009), we argue that what unites these groups is their commonality in goals, tools, and conversations – all of them focus on 'use;' that is, use-based research and use-based applications. Members of all of these groups use sociological tools to "understand, intervene, or enhance human social life" (Steele and Price, 2004). These groups differ distinctly from academic sociology in that they usually do not work just for the purposes of publishing. With their work, they intend to impact a group of people in the present day. The types of groups they want to impact differ. And, the type of impact they want to make differs.

What Do Applied Sociologists Do?

Sociological practitioners come in many colors, and occupy a wide variety of occupations. Many receive their pay as professors and teachers in institutions of higher education. Federal and state agencies or nongovernment organizations employ a large variety of practitioners. Corporate or business enterprises hire some, with a smaller minority serving as private consultants and owning firms. Some impact groups via concrete suggestions for change inside of survey findings, evaluation reports, needs assessments, legislative summaries, or editorials in newspapers. All of these reach a much wider audience than a publication in a typical academic journal, the end goal for academic sociology. In contrast, some practitioners want to engage in the action steps of change – in not just

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10517-3

evaluating or assessing, but in implementing the improvements along with group members. Hence, a continuum of engagement runs along sociological practitioners.

Clinical sociologists usually identify or diagnose a problem with an organization and then design an intervention to impact the problem. Sometimes they engage in the implementation of their recommendations, but not always. It is called 'clinical' because practitioners apply a medical frame to social groups or situations; assess, diagnose, treat, and assess again. The methodology of clinical sociology mirrors that of translational sociology. While the two are not mutually exclusive, clinical sociology, as a set of ideas and values, does not specify that a researcher participate in the action steps of a social intervention. Translational sociology does. Some translational sociologists, like public sociologists, take the findings of sociological research and try to make them useful to communities or organizations. They 'translate' the findings into goals, objectives, and action steps for groups, thereby making sociological research more useful. Some take their 'use value' a bit further by involving themselves in every conceivable step of improvement on a given issue from grant writing, to community organizing, to researching, to implementing change, evaluating the implementation, and building programs to institutionalize the intervention. In this way, translational research represents a sustained commitment to an issue and a community. Many funding agencies now require translational work.

Participatory-action researchers and community-based researchers similarly apply sociological perspectives and tools to help local organizations and community members understand and improve local issues. They partner with the vested organization or community members, or part of the project involves acquiring community participation. Hence, the terms 'community' and 'participatory.' The members, not the researchers, 'own' the project. It is their community and an issue that directly affects them, likely for years to come. Theoretically, then, the community members will lead the application of the research findings with the researcher(s) help. Unlike translational research, community-based and participatory-action researchers may not remain with a project through the implementation of all the action steps. They may not have the time, as many are college professors with students in the research. Each semester brings new classes and new students. Some schools maintain a focus on a particular neighborhood or issue across semesters by starting a 'center' or 'institute' with organizational structure and resources (i.e., a professor works to obtain grant funding) to support the research. (For a discussion on how to start a local research center, see Steele et al. (1989).)

Public and applied sociologists vary widely in direct purpose and method from all of the above groups. If you look at all of the projects in which a given public or applied sociologist participated, you would likely observe more selection in goals, clients, and methods than the above groups. For example, they may or may not work with a community organization or involve community members. They may or may not use an intervention or participate in the implementation of action steps. We largely socially construct the difference between public and applied sociology. The term 'public' is a relatively new term (largely accredited to Buroway, 2002, 2004), and public science of all kinds is currently en vogue. Whereas, the term 'applied' existed for a 100 years earlier in the United States and longer overseas. So your age and your mentors' ages largely impact whether you identify as an applied or public sociologist. That said, some tensions occasionally flare between members of the groups concerning how the two define 'client' and 'action.'

For a few applied sociologists, a client is a for-profit business from whom they receive monetary payment for services such as marketing products, satisfaction surveys, or utilization studies. This pushes the envelope for acceptable social 'enhancement' for some public sociologists. On the other hand, a few public sociologists remain too distanced from the 'public' and from concurrent, concrete action steps for some applied sociologist's taste. However, members of these groups increasingly put these differences aside and focus on the larger commonality – enhancing social life. As noted earlier, the Sociological Practice section of the American Sociological Association is now the section on Sociological Practice and Public Sociology. And the Journal of Applied Social Science (JASS) invites and regularly publishes public sociology, as well clinical and translational sociology, and community-based and participatory-action research.

Examples

To further illustrate applied sociology, we describe two projects from coauthor Jeffry Will and the Northeast Florida Center for Community Initiatives (CCI). He and his colleagues manage numerous projects annually with local community organizations to help improve services or to impact local social problems such as hunger, homelessness, high-risk or adolescent pregnancies, and substance abuse. (For more information on projects that the Center completed, see https://www.unf.edu/coas/cci/Past_Projects_/_Reports.aspx.) In one project they recently surveyed, interviewed, and observed 2117 clients of local food pantries to compose a demographic description of the client population (Will and Milligan, forthcoming). As part of that project they also documented their own observations and interactions with clients, staff, and settings. Subsequently, they informed the food bank of critical numbers from the data collection such as the percentage of clients below the poverty line and the percentage of food-insecure clients. But they also presented suggestions on organizational change that might allow the food bank to more effectively serve their client population, such as how to network better with other community organizations and how to make better use of their Web site. In another project, for a number of years CCI staff coordinated the local census and survey of the local homeless as part of a 1-day homeless count. Will and his team talked with as many people in shelters as they could find in 24 h. The survey data and the homeless count provided invaluable demographic data to the local social service agencies for planning purposes and to the state legislature for funding purposes.

Conclusion

In conclusion, many different approaches to sociological application exist. We use the term 'sociological practice' or

'practitioner' to inclusively refer to applied, clinical, and public sociologists, as well as to those who identify more with methods used across the social sciences: community-based researchers, participatory-action researchers, and translational researchers. With their work, all of these sociologists intend to impact groups of people in the present day. They primarily differ in the clients with whom they work and their level of engagement in implementing the action steps of a project. A great deal of commonality unites these groups – they all 'use' sociological tools to "understand, intervene, or enhance human social life" (Steele and Price, 2004).

Apprenticeship and School Learning: Lessons from Germany

This article is a revision of the previous edition article by H. Gruber, H. Mandl, volume 1, pp. 601–604, © 2001, Elsevier Ltd.

Abstract

Two aspects in which school prepares students for their transition to work-life are addressed. First, schools are supposed to foster their students' occupational exploration and help them in deciding and planning concerning their future vocational training (or other educational careers after graduation). Second, cognitive apprenticeship is pointed out as a way of school learning in academic domains that promises to result in knowledge relevant to everyday situations and students' future work-life, in particular. As a basis for discussing vocational orientation and apprenticeship learning at school, the apprenticeship system of vocational training is introduced in more detail.

In a narrow sense, apprenticeship is a structured training of future practitioners in the real-life context of the workplace. In this context, apprentices acquire skills and knowledge necessary to work in their field of practice, and at the same time, they are socialized into the community of practitioners. While there is not the one system of apprenticeship, the German 'dual system' that combines training at the workplace and theoretical instruction in vocational schools in a quite successful way is often referred to as a prototype and has, for instance, strongly influenced the School-to-Work Opportunities Act of 1994 in the United States (cf Hamilton, 1990).

The German educationalist Kerschensteiner (1912), a prominent representative of the Reformpädagogik (educational reform) movement, strongly contributed to the development of the German vocational training system but had more in mind than only an adequate preparation of young people for a profession and work-life. He wanted schools to socialize responsible citizens for which he considered active modes of learning in a context of real tasks and challenges superior to instruction that builds on a merely passive reception of knowledge. His didactic approach to teaching chemistry, physics, and even art mirrors crucial aspects of the vocational training of apprentices and can be seen as a first step toward ways of school learning that are referred to as apprenticeship models.

When discussing apprenticeship and school learning, two aspects are highlighted in the following that address schools' mission to guide young people toward their adult role as working citizen. First, schools are expected to support students in developing realistic representations of their competencies and interests as well as in acquiring knowledge concerning, for instance, different domains of work, apprenticeships offered, ways of being trained for jobs of interest, and the labor market. That is, schools prepare for apprenticeship by fostering students' occupational orientation. (It should be noted that basically the same processes are also relevant concerning decisions between an apprenticeship and university education or the entry into unskilled work after school graduation as well as concerning possible disciplines represented at universities or domains of unskilled work.) Second, high-school graduates are expected to leave their schools equipped with knowledge and skills that they can readily apply to their future tasks and challenges. Situated learning (Lave and Wenger, 1991) and apprenticeship models of learning (Collins et al., 1989), in particular, are concepts of instruction in school aimed at an acquisition of knowledge that is not inert (Renkl et al., 1996) but can be successfully applied to real-world situations and problems. Before these two aspects are addressed, the apprenticeship system of vocational training is described in more detail to provide a better basis for understanding to readers who are less familiar with this system.

The Apprenticeship System of Vocational Training

Being systematically trained for skilled work by way of apprenticeship has a long tradition dating back to the Middle Ages, when (then, mostly male) adolescents were introduced to the knowledge and skills necessary in a given domain of crafts or trades by helping, working together with, and being supervised by a skilled practitioner or master in the field. The efforts and costs on the part of the adult expert were balanced by the apprentice's labor and its (real) outcomes. In fact, not only was the recruitment of future practitioners based on this exchange of training and labor but to a certain extent this was also true of the economic basis of many crafts and trades that were controlled by craft guilds, which defined the goals of the training. These goals included knowledge and skills but also aspects such as attitudes and values associated with a given field. These latter aspects, in particular, but also skills and their application to novel situations, cannot easily be conveyed by explicit instruction but were trained by the cooperation of novice and expert in the mastery of the real tasks in the everyday context of their work.

While the essence of apprenticeship training thus has a long tradition, variations depending on the type of work, on the historical time, as well as on the individual master-apprentice constellation are considerable, and it is difficult to pinpoint systematic patterns of development over time. In Germany, for example, the present dual system of vocational education (BMBF, 2012; cf Hamilton and Lempert, 1996), which combines training at the workplace and part-time (1–2 days) theoretical instruction at vocational schools, was not established before the beginning of the twentieth century, and

nationwide legal regulations were established only in 1969. At present, about 550 000 young Germans, roughly half of a birth cohort, start their training in one of a little more than 340 fields of apprenticeship each year (BMBF, 2013).

High school graduates apply for an apprenticeship of their choice with a company or institution. If they get a contract, they receive a small regular income during the typically 3 years of apprenticeship, which, however, is clearly lower than regular wages of skilled practitioners in their field. Upon passing a final exam at the end of the apprenticeship time, the successful apprentices obtain a certificate. Companies working in a given domain strongly rely on these credentials when hiring new employees. Presently, companies change the apprenticeship contract into a regular employment after the exam for about 60% of their apprentices, with the likelihood of apprentices to be kept in the company increasing with company size (Pahnke et al., 2013).

International comparisons (e.g., Gries et al., 2005; Berlin, 2013) show that the apprenticeship system of vocational education is not a unique German institution but is also offered in countries such as Austria and Ireland and can exist with a purely school-based system (e.g., France, Portugal). More widespread, however, vocational education is fully integrated in the school context with varying degrees of integration of experiences at real workplaces, typically by way of internships, as can be found, for instance, in Spain, Poland, or Greece. Finally, in some countries such as the United States, on-the-job training in a learning-by-doing mode without a systematic organization and regulations beyond the expectations and rules of the employing company is the modal form of vocational training. It should be added that college education plays a sizeable role as an institution of vocational training in the US, paralleling to some extent the role played by vocational education at schools in various European countries.

Despite rules and regulations on the national level, state certificates earned upon the successful completion of the training, and controls on the part of the regional crafts and trades chambers, the inclusion of individual institutions and companies in the Dual Vocational Training System results in considerable variations in the experiences of young apprentices depending on, for instance, the domain of work or the size of the companies. Differences already start at admission to apprenticeship, where widely varying criteria apply on which the companies decide. Moreover, large companies have their own training departments and employ special training personnel for their apprentices, where training may resemble practical education in vocational schools. In contrast, apprentices trained in small crafts shops typically work together with their skilled colleagues on construction sites.

Likewise, the cooperation of companies and vocational schools tied together in the system can work out well or poorly. Some small companies might consider the hours that their apprentices spend in school wasted time (and a waste of inexpensive labor). It may also not come as a surprise that small crafts shops as well as state-financed schools can often not offer machinery and other equipment that represents the technical state of the art, which is what apprentices in larger companies typically find.

Still, young people in apprenticeships report having mostly positive experiences (e.g., being involved in real tasks, knowledgeable experts), as shown by an extensive questionnaire study including about 6000 apprentices (Beicht et al., 2009). A major critical aspect that they like is the coordination of instruction in school, on the one hand, and practical learning in the company context, on the other hand, which could be improved by more intensive communication and a better mutual understanding.

A study of advantages and shortcomings of vocational education in six European countries, which included interviews of national experts (Grünewald and Moraal, 2001), reached favorable conclusions concerning the apprenticeship system, particularly with regard to the quality and state-of-art nature of the training, the national acceptance of the training outcomes and certificates, and the motivational advantages for the young people in training. At the same time, the reported findings pointed out that the system is less flexible in matching the changes of the supply and demand sides of the labor market. Related to this point is the observation of portions of young people who find it difficult to commit themselves to an apprenticeship in only one company. These observations suggest that a more flexible solution, based on a more modularized system that allowed trainees to change companies and acquire different partial certificates might be preferable. In general, the experts question the strong orientation of the dual system toward a final certificate because this orientation is unlikely to strongly encourage a positive orientation toward lifelong (vocational) learning. Finally, it has been pointed out that the organizational and financial requirements of the German dual system of vocational training exceed those of alternative systems. Additionally, from an economic perspective, having higher shares of vocational training as in the dual system approach is related to lower unemployment rates but not to income inequalities (Busemeyer, 2011).

Vocational Orientation in School

In addition to teaching students basic skills in languages, mathematics, sciences, and other domains, as well as fostering more general competences related to, for instance, self-regulation to prepare youth for work, schools are expected to provide career guidance facilitating decision-making concerning students' future work-life and the school-to-work transition. While this task is acknowledged as important in many countries, the ways in which it is approached within schools vary widely (Härtel, 2013). Whereas in some countries, such as Finland, Greece, and Spain, specific curricular elements have been established to prepare young people for the important transition to work, these issues are more often integrated into other classes, such as social science education and ethics, in several other countries (e.g., Hungary, Malta). Yet, another path is followed in, for example, France and Poland, where special workshops are offered.

In order to arrive at sound occupational decisions, students should be helped to gain a better general understanding of work and work-life; they need guidance in thinking about such basic questions as why people should work and why school should play an important role in preparing them for their future as working adults. At the same time, students need to be encouraged to think which jobs might be best for themselves

(cf Schneider). This involves self-reflective activities and gathering information on different domains of work and more general perspectives on the labor market. These processes need to be stimulated and guided by teachers, who consider themselves responsible not only for their students' grades at school, their success in final examinations, and their school graduation but also for the occupational future of these adolescents beyond school.

Obviously, schools and teachers cannot accept the responsibility for their students getting an apprenticeship or job after leaving school, but they should support students' efforts toward an active and systematic engagement in the search for a suitable apprenticeship, program of university education, or job. What career guidance school has to promote can be referred to as occupational decision competence (Berufswahlkompetenz; Driesel-Lange et al., 2010). Instruction should include fostering an active exploration (Kracke, 1997; Kracke and Schmitt-Rodermund, 2001) of own abilities and interests as well as the world of work and specific jobs. These processes of exploration meant to promote a realistic self-representation and goal-setting should be complemented by teaching specific practical skills such as writing an application for an apprenticeship or job and by supporting students' attempts to actually apply. To this aim, schools have to be open to the world of work so that they can establish and keep up close contacts with companies in the region in order to be informed about the content and quality of apprenticeships.

Empirical research shows that internships can be a particularly powerful tool among the various strategies schools employ in their career guidance efforts. Internships are systematically integrated into efforts of occupational preparation in, for instance, Denmark, Finland, and Germany (Härtel, 2013). In Germany, for example, one or two 1- to 2-week internships are part of the mandatory school curriculum. During internships, students experience (or at least observe) situations of real work-life in its everyday context. As a side effect, internships guided by schools can contribute to students' belief that school can be a meaningful tool to prepare for real life. During adolescence, in particular, when many students feel somewhat alienated from school, such real-life experiences could be fruitful in stimulating school engagement.

However, beneficial effects can only be expected under certain circumstances. It is crucial that the internship is well designed. That is, before students apply for or start their internships, they should have had a phase of thoroughly assessing their interests and values. After this phase of self-assessment, it would be helpful for students to explore possible jobs on the Internet or by interviewing people as well as by experiencing a real application process and to then set goals for the timing of their internship. Similarly important is a guided reflection phase after completion of the internships when students are encouraged to understand whether and in which ways their occupational self-concept might have changed due to their experiences as well as to think seriously about the possible consequences of their internship experiences for their future school engagement.

The successful design of internships as well as an appropriately fruitful reflection phase requires that teachers know about the development of vocational self-concepts and how to stimulate processes of self-regulation (goal-setting, goal-pursuit, evaluation; cf Zimmerman). These teachers also need to have an idea as to which goals are realistic for which students as these students approach selecting and then enacting an internship. The latter aspects, in particular, call for values and in-class behavior of teachers that parallel the conditions of fostering intrinsic motivation as specified in self-determination theory (Deci and Ryan) such as opportunities for students' experiences of competence and autonomy as well as of positive social relations. While it is feasible to more strongly highlight corresponding elements in teacher education at universities, parallel efforts targeting the supervisors of internships at the respective workplaces are quite a challenge.

School Instruction as Apprenticeship

Fostering an active acquisition of information and competencies as well as self-regulation is a goal of learning in school that is not only relevant in career guidance. Rather, outcomes of instruction in the different academic domains addressed in class have often been criticized because they do not match the requirements of the later real-life situations to which they are supposed to be applied. The acquisition of knowledge and skills at school traditionally takes place in a situation that is isolated in two ways. First, the focus is on individual ability and performance. Second, school is designed as a peculiar learning setting for children and adolescents that is often detached from the rest of their everyday lives. It is this isolated and very limited ecological validity, in a Bronfenbrenner (1979) sense, of school learning that is pointed to as a major barrier to students being able to fruitfully employ the acquired knowledge and competences in the world beyond school.

Against this backdrop, processes of learning inspired by the apprenticeship system of vocational training have been suggested as a strategy to extend and improve instruction at school. While the basic principles had been introduced earlier, Collins et al. (1989), in particular, have conceptually specified them in their model of 'cognitive apprenticeship.' Several advantages of apprenticeship learning have been pointed out. In particular, there is often more to mastering tasks and problems in a given domain than could be easily taught by explicit instruction. In fact, there could even be aspects of which experts in the domain are not readily aware. Such implicit aspects of the knowledge and skills needed for particular vocations when modeled by an expert can be observed and picked up by learners cooperating with the expert. Moreover, apprentices sequentially go through the different steps toward the product of work in a holistic way and thus experience the meaning and usefulness of the different skills and pieces of knowledge required on the way. Likewise, learning in academic domains arranged in similar ways, such as by way of projects run in class, are also more likely to provide students with experiences that help them understand all of the intermediate steps needed as they move toward the result of their activity.

Apprenticeship learning typically follows a sequence that resembles the acquisition of procedural knowledge (Anderson, 1983) such as when learning motor skills in a sports discipline. In the beginning phase, an expert performs the different steps in the accomplishment of a task and tries to make them explicit. At the same time, he or she acts as a model to be

observed by the student. Then, the student becomes more active and performs these steps with the help of the expert. Subsequently, the expert's help steadily decreases. Finally, the learner works autonomously observed by the expert, who can comment or help if necessary. This could happen by way of direct support or by restructuring the tasks to adjust them to the level of a student's competence.

Several strategies, described by Collins (1991), play a crucial role in apprenticeship learning. Three strategies directly refer to the acquisition of knowledge in class: modeling, scaffolding, and coaching. When modeling, which is typical of the initial phase of learning, a teacher performs the tasks so that they can be observed by students. For modeling to be successful, it is important that the teacher explicitly describes and explains the purpose of what he or she is doing. This should include – as far as possible – conveying aspects of procedural knowledge involved in a declarative form. For instance, experts could verbalize considerations or problem-solving strategies that are not typically stated aloud. The method of scaffolding sets the learner into the center of activity. Depending on the progress in learning, the task is done by the learner observed and supported by the expert, who, in turn, gives feedback on the performance, hints about how to improve it, and may take over again parts of the task not yet in reach of the learners' abilities. With a decrease of direct expert activity (sometimes referred to as fading), the method of coaching becomes more important in the process: that is, continued observation of the learner so that the teacher can give helpful feedback to allow the student to accomplish the task and find solutions for upcoming problems as autonomously as possible.

Two further methods described by Collins (1991) are designed to raise the learners' awareness of their activities and improve the strategies they use to accomplish their tasks. Articulation by way of loud thinking or elicited by systematic questions helps students getting a clearer idea of strategies employed and helps learners to better organize their conceptual representations. Reflection, namely comparisons of learners' own performance with experts' performance, is also expected to result in an improved understanding. The method of exploration is meant to take the learners even one step further toward the expert level by letting them try to solve problems autonomously and to master unforeseen challenges.

Throughout the learning process, apprenticeship learning takes place in a social situation and builds on cooperation. What happens in the interaction between expert and learner is a process of coconstruction. It can, but does not necessarily, include cooperation between several learners such as conceptualized as cooperative learning.

While the apprenticeship system of vocational training is mostly a prototypical instance of situated learning (Lave and Wenger, 1991) that is taking place in an everyday work context solving real-life problems, this is obviously not the modal case of school learning in the framework of the cognitive apprenticeship model. At the same time, apprenticeship learning in school can be assumed to benefit from reaching beyond the acquisition of textbook knowledge detached from the real world. For learning to be experienced as being meaningful, a contextualization of the knowledge and skills to be acquired is helpful. To this aim, a selection of tasks and challenges reflecting everyday problems and challenges would be beneficial as would be the inclusion of approximations of real-life situations by project work and role play. By the same token, apprenticeship learning does not imply an actual extension of the learning setting to include real-world contexts, but elements such as field trips included in the curriculum would be likely to support the construction of meaning among the learners as do internships in school-based career guidance.

Apprenticeship, Anthropological Aspects

Roy Dilley, University of St Andrews, St Andrews, Scotland, UK

Abstract

Recent studies of apprenticeship have raised the method of skill-based learning in anthropology to new levels of sophistication and applied it to new areas of social life. Three predominant themes arise from this body of work: (1) apprenticeship as an indigenous form of social organization for learning specific skills and crafts, (2) apprenticeship as the way in which anthropologists have themselves undergone specific training as part of a fieldwork research method, and (3) how apprenticeship provides an opportunity to learn about learning in a variety of cultural settings, which has led to anthropological debate about theories of learning and practice.

The last 10 years have witnessed a blossoming of publications in the field of anthropological treatments of apprenticeship. When in 2001, I wrote an entry on apprenticeship for the first edition of this Encyclopedia, I commented that "over the last 10 years or more it [apprenticeship] has received much more sustained attention." (This followed a period of relatively sporadic and piecemeal contributions to the subject in the years prior to that.) That sustained attention of nearly 15 years ago has grown steadily and has now resulted in apprenticeship fast developing into one of the key areas of anthropological method and of anthropological interest about how people learn what they learn. Many new and exciting full-length studies have emerged since 2001, and apprenticeship among all manner of people – such as craft and occupational groups, trade specialists, athletes and artists, and ordinary folk engaged in everyday activity – is an ethnographically rich and theoretically innovative domain of study. Recent studies of apprenticeship have raised the method of skill-based learning in anthropology to new levels of sophistication and have developed the method into new areas of social, cultural, and economic life. The method has become almost canonical in the discipline, and has been employed widely by a range of anthropologists and other field-based researchers.

Three predominant themes in anthropological approaches to apprenticeship are still apparent in much of the contemporary literature: (1) apprenticeship as a form of social organization occurring in a variety of social and cultural contexts, (2) apprenticeship as an anthropological method of field research, and (3) apprenticeship as a domain for the analysis of social, cognitive, and bodily processes of learning. What has emerged quite clearly from a range of studies, however, is that forms of apprenticeship and modes of learning are not unchanging over time or across cultures. They are intimately linked to the economic, political, and social conditions in which learning takes place. The three aspects highlighted here will be dealt with in turn, but first some remarks to indicate how the concept of apprenticeship has been formulated in the West.

The subject of apprenticeship comes with a good deal of conceptual baggage derived from European and North American history. An institution known in ancient Greece and Rome, as well as from the early history of the Middle East, apprenticeship in Europe in the Middle Ages was regulated by craft guilds; specifically in Britain under sixteenth-century Elizabethan statutes, which were later repealed in the early nineteenth century. As a nineteenth-century institution, it received particularly bad press in Britain and the United States, where it was used as a means of poor relief for pauper children who were bound and indentured into trades so as to relieve local communities of the burdens placed on them by the poor. The lives of such children have been described as 'at best a monotonous toil, at worst a hell of human cruelty.'

Anthropological perspectives on apprenticeship and the use of child labor in non-Western cultures are confronted today by a not dissimilar problem: what relationship should be drawn between the condemnation of the use of child labor and the frequently accompanying economic poverty, on the one hand, and the recognition on the other hand that in some cultural contexts children are not excluded practically or ideologically from relations of production (see Nieuwenhuys, 1996). The dilemma over how to approach this problem is informed in part by the history of the institution in the West, and by our knowledge of the abuses to which it has been put in the past. In order for apprenticeship to be viewed as a cross-cultural concept, therefore, it has to be disentangled from our own conceptual baggage. This is not a simple or easy task.

Apprenticeship is a key institution, then, in the West's history of craft production, of capitalist industrialized manufacture, and of the transition between the two. Although Adam Smith regarded it as an archaic institution whose abolition should be welcomed, Karl Marx saw it as a form of organization that protected a skilled workforce from the logic of machine manufacture and from the subsequent deskilling of labor (Marx, 1946). Apprenticeship, viewed in the context of craft production or of industrial manufacture, is a mode of organization for acquiring trade skills and for the supply of able practitioners in a trade. (Contemporary politicians in the United Kingdom and the United States have recently started to proclaim the virtues of apprenticeship in order to fill gaps in the labor market and to maintain continuity of the supply of skilled personnel.) It also involves a relationship between a novice, who is usually a minor, and a master (usually not the novice's parent) who teaches a trade and who is recompensed for the instruction given in the form of the novice's products. Furthermore, the master stands *in loco parentis* to the novice, for he or she is responsible for the

minor's moral development and general conduct, as well as for furnishing his or her board and lodgings.

Apprenticeship as a Form of Social Organization

M. Coy's edited collection on the topic (Coy, 1989) was one of the first works by a group of anthropologists to treat apprenticeship explicitly as a social institution in comparative cross-cultural perspective. His definition of it echoes that given in the preceding paragraph, but he suggests also that it is 'rite of passage' involving 'specialized' and 'implicit' knowledge; also he emphasizes observation and participation as a mode of learning about a craft, about social relations, and about the social self and forms of cultural identity (Coy, 1989: pp. xi–xii). Marchand, however, provides us with a more recent and more nuanced description of what apprenticeship involves:

> In the exchange of 'toil' for 'ethnographic knowledge', fieldworkers are exposed viscerally to the learning environments and livelihoods of fellow workers, craftspeople and athletes … By adopting an explicitly apprentice-style method, or by actively engaging in the practices they study, [anthropologists] have developed their individual understandings about learning and knowing by 'doing' what they study. Cultivating such understanding … demands long immersion, perceptual and kinaesthetic awareness, careful reflection, persistent questioning, and a constant probing of the complex and multiple factors that constitute any field of practice. (Marchand, 2010: S10)

Being apprenticed to a master and directly participating in the practical activities of making and doing, field researchers are able to acquire first-hand experience of, and even some level of expertise in, the practices they describe, analyze, and theorize.

Ethnographic examples in Coy's volume range from North to South America, from Africa to the Far East. One of the major conclusions of the volume is that apprenticeship as a mode of social organization "displays more similarity cross-culturally and historically than any of us realised" (Coy, 1989: p. xv). Goody (1989) goes on to theorize about these commonalities, arguing that apprenticeship is a characteristic of social systems undergoing increasing differentiation in a division of labor that has breached the limits of domestic, kin-based production; systems that are undergoing structural changes by virtue of entry 'into the market.' Although there is a debate about the factors that determine the similarity of forms that apprenticeship takes across the world, some anthropologists have highlighted as well the unique features it takes in particular contexts (see Singleton in Coy, 1989; Kondo, 1990).

Coy's volume set a contemporary benchmark for developments in the study of apprenticeship: first, it provided a set of comparable ethnographic descriptions of apprenticeship systems in a range of cultures; second, it examined in depth the idea of apprenticeship as an anthropological field method. More recent work on the topic has moved debates along in a number of directions by asking such questions as: Is apprenticeship a means of imparting knowledge or of restricting it (cf. Singleton in Coy, 1989, on 'stealing the master's secrets')? What are the relationships of dominance operating within, and indeed outside of, apprenticeship systems (Herzfeld, 1995)? Is there an objective body of knowledge that is passed on to novices or is knowledge negotiated and situational (Lave and Wenger, 1991; Keller and Keller, 1996)?

The first two questions introduce the issue of power into the organization of apprenticeship, viewed as a means of the transmission of knowledge and skills to future generations. Training apprentices produces potential future competition in the form of skilled practitioners who might one day, once they are economically independent, take trade away from their former master. These issues must be seen also within the purview of the wider political economy in which the reproduction of a trade does or does not take place. The third question about the form that knowledge takes relates to whether specialists possess a body of knowledge that exists in the conventional terms in which we often think about it. Even if knowledge does not exist in the form of books, databases and so on, but in the form of oral traditions, memory, practical skill sets, and so on, the question of how the learner achieves 'knowledgeable' performance of an activity is raised in intricate and subtle ways. In many cases of apprenticeship, very little seems to be passed verbally from master to novice; in which case what is being passed on? Indeed, Trevor Marchand was struck during the course of his studies with Yemeni and Malian builders (2001 and 2009) that no templates or drawings were used in the conceptualization and realization of architectural forms. Rather, he argues, conceptualization took place through the direct physical engagement with the act of making, and ideas took shape through the use of materials and through the deployment of tools: mind and bodies and things were related within the learning environment. The development of knowledgeable practice might then be viewed in the framework of interaction and negotiation between various parties – apprentice, master, and environment – and might too be connected with bodily praxis, mimesis, and so on. These are topics dealt with more fully in the section Apprenticeship and Forms of Learning later in the article.

The significance of the master–apprentice relation is another topic of debate, especially whether it should be seen as a central characteristic of apprenticeship. Whether apprenticeship is a formal or an informal arrangement, many studies emphasize the relation between teacher and pupil as crucial to the processes and the experience of learning (e.g., Stoller and Oakes, 1987; Singleton in Coy, 1989). Cooper (in Coy, 1989) describes the constant criticism by his master of his own practice as an apprentice woodcarver, and it seems that the theme of discomfort between master and pupil is one that also recurs in many other studies (e.g., Marchand, 2001). However, following Lave and Wenger's (1991) suggestions about a 'decentred' approach that focuses on 'communities of practice' rather than single dyadic relations, some analyses have now shifted emphasis away from the master–apprentice dyad to focus on whole communities of practitioners (e.g., Palsson, 1994; Lave, 2011). The question raised here concerns how much apprentices actually learn directly from a master and how much is simply absorbed through participation with a group of skilled practitioners. There seems to be a degree of variation in the emphasis placed on master–novice relations depending on the kind of specialism being learned. Lave's studies of Liberian tailors in Monrovia, for instance,

conducted over a period of many years from the time of her first trip to the country in 1973, have highlighted the centrality of practice-based learning in which didactic teaching methods barely play any role. In her long-awaited monograph on apprenticeship, published in 2011, she analyzes the social relations created through learning among communities of fellow craft practitioners, and how she herself was immersed in this 'decentred community of practice.'

Apprenticeship as an Anthropological Field Method

The second aspect of apprenticeship is as a method of anthropological field research. An increasing number of field researchers have apprenticed themselves to practitioners of a variety of crafts, trades, and other specialties in order to acquire particular social and practical skills and to gain a deeper insight to cultural practice and processes; in short, to learn about cultural learning. (See chapters by Cooper, Coy, Dilley, and Dow in Coy, 1989 as examples, or Keller and Keller, 1996; Marchand, 2001, 2009, Stoller and Oakes, 1987; Lave, 2011; among others.) The intense interaction entailed by such participation provides a point of entry into a community and a way of learning through practice. Types of knowledge, secrets, and specific skills are also accessed, and these might otherwise remain hidden to investigations by other methods. Tedlock (1992) described how she and her husband used the method of apprenticeship successfully to learn the art of Mayan divination.

Recent studies of a wide range of crafts and other specialist activities have broadened the focus on the type of communities of practice considered by anthropologists. For instance, Venkatesan's study (2009) among Labbai mat weavers in the town of Pattamadai in South India focuses on low-status female craft workers, who are not driven by a passion to learn weaving but by a need to take it up primarily for economic reasons. Within the context of the anthropology of work, he analyzes the relationship between the processes by which a skill is learned on the one hand, and knowledge about the possibilities and ramifications of the skill on the other hand. Their labors cause the women physical pains and debilitating problems in the long term, and their regular participation in the activity exposes them to wider social values and attitudes, and reinforces gendered identities and social class positions. Girls learn weaving at home in a piecemeal fashion of instruction, observation, imitation, and 'having a go,' a training that is devoid of any formalized elements. Although the mats are woven by poor Muslim women of low-social status, their products are bought by elite Tamil Hindus and other affluent sectors of the population. Paradoxically, the women are lauded as producers of fine traditional craft objects, but are marginalized because of the occupation they follow.

One of the more remarkable studies of apprenticeship of the last decade has been Loïc Wacquant's intriguing, agonizing, and revealing investigation into the world of boxing as practised at a gym in a black neighborhood in Chicago's south side (Wacquant, 2004). For 3 years, he immersed himself in the pugilist's art, never intending at the outset to step into the ring but eventually succumbing to the lure of the gloves. His training regime was strenuous, the discipline severe; the drills of shadow-boxing and sparring against other amateur boxers transformed his body, his mind, and his awareness of himself. Once trained and fit, he entered the Golden Gloves tournament, the city's most prestigious amateur event, as a competitor, and he gives us a compelling account of his participation in it. Nicknamed 'Busy Louie' by the owner of the gym, Wacquant established a sound reputation for himself as a boxer, and he learned not only the art of boxing but also how the gym worked as a social space, and how the controlled violence of the gym stands in contrast to the violence on the streets of Chicago's south side. While his reporting of events, personalities, and social relations of Chicago's world of boxing is evocative and persuasive, Wacquant develops a theoretical line of argument that attempts to capture a 'carnal sociology' within a theory of practice. He does so by developing Bourdieu's concept of habitus, which embraces the idea of embodied knowledge, the type acquired through his training as a boxer. I will return to this theme.

Apprenticeship as a field method is not without its critics, who point out the methodological dangers of compromising 'objectivity' and succumbing to partiality. Few anthropologists, however, rely totally on this method and often use other techniques to investigate wider, macro social processes beyond the workshop or specific context of learning. Cooper discusses the 'fiction' of apprenticeship: the requirement for fieldworker and fellow practitioners to enter into a pretence and to know when the pretence ends. A kind of 'enforced schizophrenia prevails' (Cooper, 1989: p. 138). The 'enforced schizophrenia' inherent in the method allows for a continual methodological movement in and out of roles, and indeed sets up a distance from, as well as an engagement with, the subjective and experiential aspects of being apprenticed. Apprenticeship has of course much in common with traditional participant-observation, in which the fieldworker is as much a kind of 'cultural apprentice' as he or she is a detached observer (Coy, 1989; see also Goody, 1989; Keller and Keller, 1996; Palsson, 1994 on this comparison). Apprentice participation is thus an extension of traditional anthropological methods of participation and observation, and is pertinent to the investigation of particular kinds of activities that may be closed, specialized, or in some way inaccessible. The method also opens up areas of investigation about the nature of social and cultural learning in specific places; and this is a topic that can only be studied by researchers actually having a go at the process in question.

Apprenticeship and Forms of Learning

The third aspect of apprenticeship is the way it has been linked to the anthropology of education (see Pelissier, 1991) and to the analysis of cultural theories of learning. Lave and Wenger (1991) have reworked this area to propose a shift away from the study of apprenticeship per se to the more general idea of 'situated learning' and 'legitimate peripheral participation,' in which the learning process is embedded in 'communities of practice.' The analysis of cognitive activity is,

therefore, firmly placed back in the domain of everyday life. Their work reviews a range of learning contexts from Yucatec midwifery to the US Navy, and it raises questions about the relationship between participation and knowledge.

This relationship can be seen as problematic in that much of the knowledge learnt in such contexts is not verbalized and indeed is nonpropositional in nature. What is learnt is gained through mimesis, practice, and repetition of tasks performed routinely by skilled practitioners. Bodily knowledge, bodily techniques, manual skills, and aesthetics have now become the focus of study. William Hanks made a similar point some time ago in his foreword to Lave and Wenger's *Situated Learning* when he suggested that the apprentices' ability to understand a master's performance depends not on their possessing the same representation of it, or of the object it entails, but rather on they being engaged in the performance in congruent ways (1991: p. 21). Examples of this type of approach are Marchand's studies of master builders and of British woodworkers (2001, 2009, 2010, in preperation), in which he talks of the production of knowledge through the 'shared performance' of everyday mundane occurrences; or Greg Downey's work among skilled practitioners of Brazilian capoeira (2005); or Wacquant's examination of his own apprenticeship as a boxer among prizefighters in Chicago (1998 and 2004). Novices learn through their bodies as well as their minds, and the bodily discipline of a trade also creates moral and aesthetic sensibilities. Moreover, these learning processes are not just about practical skills or producing objects, but are also concerned with the creation of cultural identities and selves. As Kondo points out with regard to Japanese artisans, work involves self-realization, a "polishing of self through hardship," for "a mature artisan is a man who, in crafting fine objects, crafts a finer self" (Kondo, 1990: p. 241). These studies suggest, therefore, that the rigid Cartesian distinction between mind and body, thought and action, needs to be critically reexamined.

Studies by a number of anthropologists into the way in which minds, bodies, thoughts, action, tools, and environment come together in learning new skills and in perfecting the performance of them have led to a debate about how best to theorize practice, process, and structure. Recent work in particular contains a critique of Bourdieu's concept of habitus as a means through which embodied learning occurs. This critique revolves around the central idea that practice-based learning involves imitation and mimicry; a performer imitates a practice and repeats it until the action has been made habitual and perfect. But this is not blind mimicry, an unthinking imitation, a system of rote learning without conscious engagement with the process of skill acquisition. Repetition is not repetitive; rather embodied learning involves awareness by the practitioner of his or her movements and gestures, and an opportunity to reflect on, alter, and finesse the performances of an action as it is reworked and replayed. (It is here that the possibility of innovation and creativity can emerge.) In other words, there is a continual and conscious process of evaluation and adjustment, and this idea challenges the central assumption of practice theory: namely, that mastered practices are executed unreflectively. Anna Portisch's study of felt carpet production among Kazakh women in western Mongolia effectively illustrates the point that carpet-makers keep a number of aspects of the repetitive process of production in their awareness at the same time (2010). The limitations of practice theory, as suggested here, have been pointed out also in the works of Marchand (2010) and Downey (2005).

Greg Downey conducted research among practitioners of capoeira for more than 10 years, taking lessons in Brazil from masters who passed on their expertise in spoken and unspoken ways. In his book entitled *Learning Capoeira: Lessons in Cunning from an Afro-Brazilian Art* (2005), Downey examines the effect that bodily training in this form of dance and martial art has upon the performers' perceptions of self, of others, and of their social interactions within the 'ring,' or *roda*, where the game takes place, as well as outside the ring in their daily lives. Downey takes his analysis beyond Bourdieu's theory of practice by arguing that habitus is not beyond the realm of conscious awareness, and by drawing on recent developments in psychology and neurosciences that deal with the effects of physical education on human perception and self-awareness.

One of the major developments in the study of apprenticeship, therefore, has been that although anthropologists have long acknowledged that people (including themselves) learn through participation, they have now come to shed light on the cognitive processes taking place during learning, and the way in which mental representations are constructed through skilled performance, and how in turn those representations inform performances.

Trevor Marchand has emerged as one of the leading figures in the study and analysis of apprenticeship as a method of anthropological inquiry, and as an avenue into the investigation of the process of learning. He conducted his first apprenticeship among minaret builders in San'a, Yemen, which resulted in a monograph published in 2001 entitled *Minaret Building and Apprenticeship in Yemen*. Later, he worked as a laborer and an apprentice as he conducted research among mud masons in the town of Djenne, Mali, which was published in a monograph entitled *The Masons of Djenne* in 2009. Marchand's apprenticeship allowed him not only to come to an appreciation of how learning occurs through participation among masons, but also to glimpse into the esoteric arts that surround the performance of masonry, arts that are used to protect craftsmen and laborers at work and ensure the safe and proper conduct of the occupation. His third project begun in 2005 is still ongoing and it employs similar apprentice-style field methods to the earlier studies. This research, however, is on carpenters and furniture makers in London, and it engages with skill-based practice learning among trainees at the Building Crafts College in East London. His ethnography details social relations, professional aspirations, and economic challenges faced by his fellow woodworkers as they attempt to gain the skills necessary to set themselves up as professionals. The research findings will appear in a forthcoming book entitled *The Pursuit of Pleasurable Work*. This project (along with his earlier ones) has offered Marchand an opportunity to develop a theory of embodied cognition and communication, which has drawn on ideas taken from current research in neuroscience. His aim is to grasp the relationship between the brain, the human hand, and the tools used in carpentry, and he has proposed new methods of data collection to meet this challenge. Going

beyond the use of participant observation, interviews, and so on, Marchand has employed in particular digital recording technology and motion-capture analysis software to produce a database for examining tool use, human gesture and movement, and the expression of craft skills in the making. His goal is to advance a refined anthropological theory of embodied knowledge that directly challenges the nature of the concept of habitus as conceived in Bourdieu's practice theory.

Apprenticeship has looked specifically at how ways of knowing are constructed and how individuals participate in social relations of learning to acquire new skills, abilities, expertise, and knowledge. What has not received so much attention is how these relationships of learning are predicated on conceptions of ignorance, and how the process of learning and knowing mutually construct correlated domains of ignorance and nonknowledge. While much research over the last 20 years or more has quite rightly and very productively been conducted into the ways in which knowledge is made and how people learn skills and construct their own ways of knowing, there is a flip-side to all of this. And this flip-side concerns not-knowing, nonknowledge, and ignorance. Not-knowing is a precondition for the organization and distribution of relations of learning within specific contexts. It is not only the ground on which learning takes place (knowledge in one sense banishes ignorance), but it also informs the larger field of relations about who knows what and, as importantly, who is ignorant of what. For example, weavers in Senegal, West Africa, learn the skills of weaving in the context of formalized apprenticeships. But members of other social ranks who would not consider it their proper role to practice such a craft – indeed, they would deem it beneath them to do so – desire to remain ignorant of the techniques, skills, and abilities of weaving. This ignorance can be 'real' in the sense that nonweavers are usually excluded by master weavers from entry into an apprenticeship; but this ignorance can also be contrived in the sense that those living cheek-by-jowl with weavers may observe, pick up, and absorb the ways of the weaver by simply being in their presence for long periods. These 'voyeurs' of the weaver's art, as it were, often feel compelled to ignore what they have witnessed; they turn their eyes away from what is there for them to observe. Their ignorance maintains an appropriate social boundary and allows for the pretense of the monopoly on craft skills being contained within the domain of formalized apprenticeship.

The concept of apprenticeship is a matrix connecting a set of keystone issues within the contemporary frame of social and cultural anthropology. When employed in cross-cultural comparison, it demands explanations for its apparent commonalities across a wide range of social settings as well as for its cultural particularities specific to place or time. The practitioners of apprentice field methods have raised questions about the delicate balance between subjective participation and distanced observation that lie at the heart of empirical fieldwork procedures: indeed, apprenticeship suggests a way of bridging this distinction. As a domain of inquiry, apprenticeship highlights cultural conceptions of knowledge and the processes of learning, of embodiment and bodily praxis, of self and identity formation. Also it highlights the need to examine the connections between knowledge and power in dynamic interactive contexts embracing both individual practitioners situated in different social roles and communities of skilled actors whose practices create wider webs of relations. These concerns about knowledge and power extend, moreover, beyond the parochial boundaries of the workshop or place of learning to the broad social world in which apprenticeship takes place.

Abstract

Qualification on the one hand and integration and enculturation on the other hand are among the most important functions of schools for the society as well as for the individuals. School learning thus should teach students facts and skills that are necessary for later life. However, evidence exists that school learning often is far away from application situations out of school. Critics have argued that it frequently leads to knowledge that is inert and thus cannot be used for solving real-world problems. A plausible reform idea is to make school learning resembling learning out of school. This article reviews arguments and evidence for and against this proposition.

Apprenticeship Models as Solutions for Problems with School Learning

Resnick (1987) identified four principles in which learning in and out of school differ: (1) Individual cognition in school versus shared cognition outside. Learning in school focuses on individual performance; that is, students have to work in isolation. In contrast, learning out of school usually focuses on shared knowledge and cooperative problem solving. (2) Pure mentation in school versus tool manipulation outside. School learning focuses on abstract mental activities that have to be done without the use of any external support like one's own notes or Internet research systems. In contrast, learning out of school heavily relies on individuals' ability to use adequate tools in an adequate way. (3) Symbol manipulation in school versus contextualized reasoning outside school. With its focus on symbol-based reasoning, school learning often lacks close connections to events and objects in the daily world that are characteristic for learning out of school. (4) Generalized learning in school versus situation-specific skills outside. School learning aims at the acquisition of general, widely usable principles, whereas learning out of school focuses on solving problems that actually arise at places and contexts the individual is situated in.

The analysis of discrepancies between learning in and outside the school includes criticisms of present school instruction concerning both the qualification function of school and its integration and enculturation function. Similar arguments were brought forward by the German 'Reformpädagogik' a century ago. Alternative instructional models developed in these years are closely related to the proposals nowadays made by situated learning theorists. One common principle is that students participate in more advanced individuals' activities and thus increasingly get part in the community of practice. In such *apprenticeship models of learning*, besides knowledge students have to acquire the ways of thinking in communities of practice, they have to become part of what constitutes the respective epistemic culture (Knorr-Cetina, 1999).

A number of situated learning models have been developed in order to decrease the discrepancy between learning in and out of school and to avoid the emergence of inert knowledge (Renkl et al., 1996). In each, students learn within complex contexts like apprentices by solving authentic problems in a community of practice. The approaches are based on the idea that knowledge is socially shared so that plain teaching of 'objective' knowledge does not suffice because each working situation includes demands for adaptive problem solving (Derry and Lesgold, 1996). The view that knowledge in principle is situated in the environment within which it was acquired is the perspective of *situated learning*.

Theoretical Background: 'Reformpädagogik' and Situated Learning

Many aspects of the mentioned situated learning approaches resemble concepts of the *Reformpädagogik*. When the agents of this German educational movement expressed their ideas a century ago, they were well aware of developments in the Deweyan Chicago school (e.g., the project plan; Kilpatrick, 1922), and vice versa. Reformpädagogik criticized the 'book school' in a similar way the school learning nowadays is criticized. The central counter-idea then was the 'work school,' most prominently proposed by Kerschensteiner (1912). He emphasized the importance of manual work that should be closely tied to mental work. Among his school reforms was the introduction of school kitchen instruction and school garden instruction. Based on authentic activities, students learned chemistry, physics, physiology, and mathematics. Instructional questions usually were not posed by the teacher, but rather by the students when working on problems. Such self-regulated activity reduced the discrepancy between school and everyday life. Work school no longer was an *Ersatzwelt* in which *ersatz activities* had to be carried out. Since the problems posed were of relevance to the students' life outside school, besides skills and knowledge learners acquired relevant social attitudes and a sense of responsibility as members of society.

Kerschensteiner (1912) was extremely concerned about the question whether school prepared for later professional life. He thus initiated the German vocational training system, the *dual system*, which is a form of training tied to the workplace with

supplementary teaching in the compulsory, part-time vocational school. In this system, not only manual work is stressed, but the notion of work can also be ascribed to cognitive learning processes or, in terms of Gaudig (1922), 'free mental work.'

Many of the Reformpädagogik ideas were theoretically reconsidered in the situated learning movement under cognitive psychological and constructivist perspectives. Five major instructional principles can be identified (Gruber et al., 1995).

Learning by Solving Authentic Problems

In problem-oriented learning, an authentic, rather complex problem marks the starting point. Its function is not only to motivate students. By embedding the learning process in meaningful contexts, it also aims at knowledge acquisition through application instead of abstract teaching. Knowledge is conditionalized to application conditions from the beginning.

Multiple Perspectives

Domains are analyzed from multiple perspectives and multiple contexts in order to foster multiple conditionalization. Preventing the emergence of dysfunctional oversimplifications and fostering active abstraction processes are the main instructional functions, thus supporting flexible use of knowledge and skills.

Articulation and Reflection

Externalizing mental processes enables students to compare their own strategies with those of experts and other students. Articulation facilitates reflection and thus fosters the decontextualization of acquired knowledge.

Cooperative Format

Cooperative learning facilitates the comparison with experts and peer learners. In addition, cooperation skills are useful in later professional life.

Learning as Enculturation

A particular function of learning is to become enculturated into communities of practice. To achieve this, students have to get a sense of authentic practice. They have to acquire functional belief systems, ethical norms, and the tricks of the trade.

These principles of situated learning have been realized in several instructional models. The most convincing of these models is cognitive apprenticeship.

Microanalytic Use of Apprenticeship in School Learning: The Model of Cognitive Apprenticeship

The apprenticeship metaphor for designing situated learning arrangements has its origin in craft domains: for example, tailoring or midwifery. Collins et al. (1989) adapted the concept for cognitive domains. In cognitive apprenticeship as in craft apprenticeship, students are introduced into an expert culture by authentic activities and social interactions. Important is the sharing of problem-solving experiences between students and mentors (i.e., experts, teachers, or advanced students), thus negotiating their understandings and actions through dialogue. Since in cognitive domains mental activities prevail, the explication of cognitive processes is extremely important in order to publicly expose knowledge and thinking processes involved in the cooperative problem solving (Simons and Ruijters, 2004).

The core of cognitive apprenticeship is a particular instructional sequence. Learning takes place in sequenced learning environments of increasing complexity and diversity. In early stages of learning, mentors provide overall direction and encouragement. As students improve, mentors gradually fade support, encouraging students to work and think more independently. At all phases of apprenticeship, the mentor is assigned an important role as a *model* and as a *coach* providing *scaffolding*. However, the student has to increasingly take over an active role, as the mentor gradually *fades out*. *Articulation* and *reflection* are promoted by the mentor in order to persist on externalization of cognitive processes.

This instructional sequence supports students to increasingly work on their own (*exploration*) and to take over the role initially held by the mentor. Lave and Wenger (1991) similarly described professional learning in nonexplicit learning contexts as development from legitimate peripheral participation to full participation. Learning is thus not confined to the acquisition of knowledge or skills, but a social process of enculturation by getting a full participation in a community of practice that can cope with the problems typical for the domain in a flexible manner. Considering learners as apprentices ascribes them a novel role. From the beginning, they are active participants in authentic practices instead of passive recipients.

Empirical evidence exists that cognitive apprenticeship learning supports the acquisition of applicable knowledge in a variety of domains (e.g., programming and medicine). However, successful learning is not guaranteed. High demands are made on learners, so that careful instructional support is necessary (Gegenfurtner et al., 2009).

Macroanalytic Use of Apprenticeship in School Learning: Communities of Practice – Implementation of Apprenticeship in School Systems

Cognitive apprenticeship stresses that learning performance, like all authentic cognitive activity, is socially constituted. Learning environments inevitably are part of a complex social system, and the structure and meaning of learning processes are substantially influenced by that system. It is unlikely that an adequate understanding of learning processes can be developed without taking the social context into consideration in which learning processes are situated. Conceiving learning as becoming enculturated into communities of practice thus concerns not only the individual processes during learning but also the implementation of learning environments in large social contexts, frequently denoted as the prevailing 'learning culture.' Taking the apprenticeship idea seriously, such macroanalytic concepts of learning are inseparably connected with microanalytic analyses of learning processes and, at the same

time, learning has to be bound to application situations and has to be integrated into a large system with adequate learning culture.

The principle of the dual system of vocational training in Germany tries to fulfill these requirements. It includes simultaneous qualification at two learning locations, namely vocational school and workplace. Thus, school learning and professional practice are closely tied, so that opportunities for learning by doing are realized.

In medical education, the principles of situated learning are applied in the common teaching format of bedside teaching. The idea is that students learn in an interactive manner to treat a real patient. The authenticity of such a learning environment should provide the opportunity to acquire medical as well as interpersonal skills relevant for the profession (Eraut, 2000). The conditions of the work environment need to foster learning, and therefore the environment should be designed accordingly (Festner and Gruber, 2008; Gierk and Harendza, 2012; Spencer, 2003). In practice this is not always easy to achieve. In a study of guidance at work, Filliettaz (2011) investigated the pedagogical aspects of initial vocational training in the context of the Swiss Vocational Education and Training (VET) system. Apprentices interacted with various colleagues in the workplace, and it was examined how apprentices were guided and supported by experienced workers. The results indicate that the pedagogical quality of guidance in the workplace needs to be considered in order to increase efficiency during the apprenticeship and facilitate gradual transitions into work experiences.

Efforts to implement the dual system in countries other than Germany (Harhoff and Kane, 1997; Heikkinen and Sultana, 1997) (Austria, Switzerland, Denmark, and parts of Italy) showed that many organizational preconditions are required, such as flexibility of enterprises in the adaption of the system, an elaborated widespread school system, adequate teacher education, and so on. The dual system cannot serve as panacea if the learning culture within a society is not readily prepared. Additionally, modern development of workplaces (such as globalization of enterprises and new principles of working organization) yield difficulties for the dual system. New approaches in educational research are being developed as response to emerging imbalances between the learning locations, namely school and workplace. For example, 'discipline and location-crossed training' aims at implementing new ways of cooperation between learning locations.

Outlook: What Remains of Traditional School Learning?

The view that knowledge is essentially situational has major educational implications. Learning is regarded as a process of enculturation and means to take part in a particular community of practice, to get acquainted with the culture of the community, the jargon used, the beliefs held, the problems raised, and the problem-solving methods used. This entails the notion of apprenticeship for learning.

Traditional school learning is accused of producing inert knowledge as students fail to transfer their knowledge to tasks embedded in contexts other than school settings. Lave (1988) argued that traditionally school is treated as if it were a neutral place, with no social and cultural features of its own, in which abilities are acquired that can easily be transferred later to any other situation.

As mentioned above, there is evidence for the phenomenon of inert knowledge. However, this evidence not necessarily requires the importance of traditional school learning to be denied. Even if there exist resources other than teaching through which apprentices acquire their skills, apprenticeship is not the only effective means of learning. The academic context of school learning proves useful for a variety of learning situations. It is very likely that an interaction exists between learning purposes and preferable learning contexts. Educational psychology has to carefully decide which kind of learning context is appropriate for which kind of learning, and should take into consideration research results for the design of school learning as well as for the design of teacher education.

Thus, the notion cannot be maintained that traditional school learning should be entirely abolished. However, it is worth to analyze under which conditions apprenticeship models are an attractive alternative to traditional school learning. For which kinds of skills and knowledge, in terms of their complexity (i.e., elementary, intermediate, or sophisticated) and nature (i.e., declarative, procedural, or strategic), is apprenticeship deemed necessary? Which means help students to benefit most? These questions have to be addressed in future research in order to determine the role apprenticeship can and should play in future so that an adequate balance between traditional school learning and situated learning will be found.

Apraxia

Georg Goldenberg, Bogenhausen Hospital, Munich, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The term apraxia refers to 'higher level' disorders of motor control. The core manifestations of apraxia affect the imitation of gestures, the performance of communicative gestures, and the use of tools and objects. All of them occur predominantly after left brain lesions and are frequently, though not invariably, associated with aphasia. In contrast to elemental 'low level' motor disturbances, they affect not only the side of the body opposite to the cerebral lesion but also the ipsilateral side.

The term apraxia refers to 'higher level' disorders of motor control. There is, however, no general agreement as to what counts as a high- or a low level of motor control. Consequently, the history of apraxia has brought forward a wide variety of diverging definitions and classifications of apraxia. The most influential of them was proposed some 100 years ago by the German psychiatrist Hugo Liepmann (Liepmann, 1908; Goldenberg, 2003). Liepmann based a classification of apraxia on a model of voluntary action that distinguished two consecutive phases. The first is the creation of mental images of the intended action and the second its transduction into appropriate motor commands. Their sequence constitutes a path leading from high to low levels of motor control. Liepmann proposed to name disturbance of the first phase 'ideational' and that of the second phase 'ideokinetic' apraxia. He equated this theoretical model with an anatomical schema. He reasoned that mental images of intended actions are predominantly visual and therefore located in posterior brain regions whereas motor commands are sent out from the precentral motor cortex. The transduction of ideas into motor actions thus corresponds to the transmission of signals through white matter tracts leading from the occipital to the frontal lobe. Parietal lesions interrupt this posterior-to-anterior stream of action control and are thus the prime cause for ideokinetic apraxia.

The opposition between mental image and motor execution of actions has not remained the only attempt to conceptualize a dichotomy between high and low levels of motor controls. Other proposals set autonomous action in opposition to environmental dependency, coping with novelty to routine action, abstract symbolic gestures to material interactions with concrete objects, or planning of goal-oriented action sequences to single actions (Pick, 1905; Denny Brown, 1958; De Ajuriaguerra and Tissot, 1969). Arguably, the dichotomy between high and low levels of action control ultimately refers to a mind–body dichotomy that constitutes a driving force behind many attempts of conceptualizing and classifying variants of apraxia (Goldenberg, 2013). The formulation of the dichotomy that fits best with the terminology of cognitive neurosciences today would be the opposition between cognitive and motor aspects of action control.

In view of the diversity of theoretical accounts of apraxia it is not surprising to note a similar diversity of opinions concerning the range of clinical symptoms that should be classified as apraxia. For example, defective imitation of meaningless gestures was central for the understanding of apraxia for some authors (Kimura and Archibald, 1974; Goldenberg and Hagmann, 1997) but considered as irrelevant by others (Geschwind and Damasio, 1985). Likewise, 'constructional apraxia' that had been a central piece of theories of apraxia in the midst of the twentieth century (De Ajuriaguerra et al., 1969) is hardly included into surveys of apraxia any more.

There is, however, a core of symptoms that have already been emphasized by Liepmann and that were recognized as belonging to apraxia by a majority of subsequent authors. They concern three domains of human actions: The imitation of gestures, the performance of communicative gestures, and the use of tools and objects. All of them occur predominantly after left hemisphere brain lesions and are frequently, though not invariably, associated with aphasia. In contrast to elemental 'low level' motor disturbances, they affect not only the side of the body opposite to the cerebral lesion but also the ipsilateral side. All results reported in this article refer to actions of the hand ipsilateral to the lesion.

Figure 1 gives an overview of critical locations for each of the manifestations. A first conclusion from inspecting them is that they vary widely and there is no single region that is involved in all of them. In other words, there is no indication of a 'praxis center' or, respectively, a 'praxis system,' disturbance of which underlies all manifestations of apraxia. We will discuss underlying mechanisms and neural substrate for each of the manifestations separately but then ask again whether there are substantial communalities unifying them.

Imitation

For the clinical examination of apraxia, testing of imitation has the great advantage of being an essentially nonverbal task. The observation that patients with left hemisphere brain damage have nonetheless more difficulties than controls or patients with right hemisphere brain damage contradicts attempt to explain apraxia as a mere consequence of aphasia. The theoretical interest goes beyond the corroboration that apraxia is an independent sequel of brain damage. To Liepmann, disturbed imitation yielded the main support for his contention that patients were unable to transmit a correct image of the intended gesture into appropriate motor commands. The view that defective imitation indicates a problem of motor execution has been upheld by influential modern authors. For example,

Figure 1 A summary of locations of different manifestations of apraxia: shading of the whole hemisphere does not exclude the possibility of more fine-grained localizations within the hemisphere, but indicates that there are no firm empirical data for delimiting the critical areas. Adapted from Goldenberg, G., 2007. Neuropsychologie – Grundlagen, Klinik, Rehabilitation. 4. Auflage, München, Jena: Elsevier: Urban und Fischer, p. 149, by permission of Elsevier.

De Renzi (1990: p. 246) wrote: "Since the examiner provides the model of the action and the patient must simply copy it, errors can only be due to an executive deficit."

Defective translation of the mental image of the intended gesture into motor command should affect gestures independently of the origin of the mental image. Consequently, patients who have problems with imitation should also fail when motor actions of similar complexity are produced on verbal command as, for example, when patients demonstrate pantomimes of tool use. This prediction is refuted by observations of patients with visuoimitative apraxia. They fail imitation of meaningless gestures but perform pantomimes of object use and other meaningful gestures on command flawlessly (Goldenberg et al., 1997). They may even achieve correct imitation of meaningful gestures by first understanding their meaning and then reproducing them from long-term memory.

A plausible account of these dissociations can be given by the assumption of two parallel routes for imitation. One passes via semantic memory where the meaning of a gesture is recognized and from where it can be reproduced. This route cannot support imitation of meaningless gestures because they are not represented in semantic memory. A second route connects the visual percept of the shape of demonstrated gestures directly with the motor programs for reproducing the same gesture. This route can accommodate both meaningful and meaningless gestures. As meaningful gestures can take the alternative deep route, destruction of the direct route will result in a selective deficit of imitating meaningless gestures, that is, in visuoimitative apraxia (Rothi et al., 1991; Tessari et al., 2007).

The proposal of a direct route connecting perception of motor actions with their motor reproduction has gained popularity by the detection of 'mirror neurons' that fire both when monkeys or human beings see an action and when they perform the same action (Rizzolatti et al., 2002).

The directness of the route from perception to motor execution of gestures is, however, called into doubt by the finding that patients who show apraxia for the imitation of meaningless hand postures are also impaired when they are asked to replicate the hand postures on a mannikin (Goldenberg, 1995). As the motor actions of manipulating a mannikin are very different from those of imitating the target posture on the own body, correspondence between demonstration and replication of the gesture must be established by an intermediate representation that is distinct from the motor action for achieving the target posture.

The plausibility of a direct route from perception to imitation of gestures is further undermined by the observation that defective imitation of meaningless gestures can be body-part specific depending on the location of the causal lesion. **Figure 2** shows examples of hand-, finger-, and foot postures. Whereas defective imitation of hand postures is nearly exclusively bound to left hemisphere lesions, imitation of finger- and foot postures is also susceptible to right hemisphere lesions (Goldenberg and Strauss, 2002). Within the left hemisphere, defective imitation of hand postures is a symptom of parietal lobe damage whereas defective imitation of finger postures is more likely to be due to inferior frontal lesions (Goldenberg and Karnath, 2006). The attempt to reconcile the body-part specificity of causal lesions with interruption of a direct route from perception to motor execution of gestures would lead to the rather unlikely conclusion that there are multiple direct routes distributed across both hemispheres. The improbability of such multiplication prompts the search for other possible mechanisms underlying defective imitation.

I proposed that a crucial intermediate step between perception and motor execution of meaningless gestures is body-part coding. Body-part coding segments the body into distinct body parts that are combined for creation of gestures. It thus reduces the visual manifold of the gesture to simple spatial relationships between a limited set of defined elements. For example, in **Figure 2**, the left upper panel of each kind of gesture can be coded as 'fingers 2, 4, and 5 extended,' 'thumb touches inferior side of nose with back of hand toward face,' and 'heel touches instep.' Body-part coding can accommodate novel and meaningless gestures to combinations of familiar elements and alleviates the load on working memory for holding the gesture from its perception to the accomplishment of its reproduction. Furthermore, translating the gesture's visual appearance into relationships between body parts produces equivalence between demonstration and imitation that is independent of the different modalities and perspectives of perceiving and moving one's own, other persons' or a mannikin's bodies.

According to this hypothesis, body-part coding is bound to integrity of the left inferior parietal lobe. Left frontal and right hemisphere regions come into play when imitation puts additional demands on visuospatial analysis of demonstrated gestures or on selection between perceptually highly confusable postures.

Positions of the hand relative to parts of head and face put high demands on body-part coding because they involve

Figure 2 Examples of finger, hand, and foot postures used for imitation of meaningless gestures. Reprinted from Goldenberg, G., 2007. Neuropsychologie – Grundlagen, Klinik, Rehabilitation. 4. Elsevier, Auflage, München, Jena. Urban und Fischer, p. 145, by permission of Elsevier.

a multitude of different body parts like chin, lips, back and flanks of the nose, cheek or ears, palm and back of hands. By contrast, finger postures are, with a possible exception for the thumb, constituted by a set of uniform elements, which differ only in their serial position. Thus, body-part coding of finger postures can be reduced to numbering extended and flexed fingers according to their serial position from index to small fingers. On the other side, the body parts involved in hand postures are perceptually salient and unmistakable, whereas the uniformity of fingers makes their distinction difficult and demands evaluation of the entire hand in order to determine the spatial position of the fingers that are bent or extended (Goldenberg et al., 2009). Finally, foot gestures put high demands on both components of imitation. They involve a considerable number of conceptually different body parts like ankle, heel, calf, big toe, and little toe that are, however, perceptually less salient than the parts of the face determining the hand postures. Their perceptual analysis is further complicated by the three dimensional overlapping and consequent occlusion of sight of one leg by the other (see **Figure 2**).

In sum, modern research does not support Liepmann's contention that defective imitation testifies insufficient transformation of mental images into motor commands nor that it results from interruption of a direct route from perception to motor execution. Indeed motor mechanisms seem to play a subordinate role for this manifestation of apraxia. Although the gestures themselves are meaningless, their imitation taxes the cognitive rather than the motor side of action control.

Communicative Gestures

Hundred and fifty years ago, in the very early days of cognitive neuroscience, Paul Broca noted in his description of the aphasic and hemiplegic patient 'Tantan' that he was unable to manifest his ideas or desires other than by movements of the left hand but frequently made incomprehensible gestures (Broca, 1861). Ten years later, the German psychiatrist Finkelnburg (1870) described an aphasic woman who had been raised as a devout catholic but now failed to make the sign of the cross after the grace. "When asked by her surrounding to make it, she hesitantly reached sometimes behind the ear, sometimes to the neck until it was demonstrated to her. Then she imitated it exactly." From this and other observations of nonverbal communicative impairment of aphasic patients Finkelnburg concluded that these patients suffer not merely from loss of speech but from a more profound inability of communication, which he termed 'asymbolia.'

Liepmann assimilated the deficiency of communicative gestures into his classification of apraxia. He thought that performance of communicative gestures shares with defective imitation the need to perform movements 'wholly from memory' without support by instrumental interaction with external objects, and hence brings forward the inability to transmit a mental image of an intended action into appropriate motor command. Consequently, he subsumed disturbance of imitation and of communicative gesture under the common heading 'ideokinetic apraxia' that was later renamed into 'ideomotor apraxia' (Morlaas, 1928). The existence of 'visuoimitative' apraxia, discussed in the previous section, constitutes a strong argument against the alleged communality. It is complemented by observation of patients who fail the production of communicative gestures but can imitate flawlessly, like Finkelnburg's catholic lady (Barbieri and De Renzi, 1988).

Broca and Finkelnburg had derived their conclusions from observation of spontaneous gestures of aphasic patients. Liepmann introduced two modifications of the assessment procedure that are still followed by the majority of authors today.

The first modification was the replacement of observations of spontaneous gestures by examination of gestures on command. The production of communicative gestures on command creates a conflict between the message of the requested gesture and the concrete communicative situation. As the examiner knows in advance the message that is expressed by the patient's gesture, the actual communicative function of its production is at best confirmation of the patient's willingness to comply with the instruction. Difficulties of aphasic patients to produce gestures that are unrelated to the concrete situation have been central to the argument that they suffer from a general loss of 'abstract attitude' and that apraxia is only one manifestation of this pervasive loss (Goldstein, 1928).

A second modification was the restriction of the examination to gestures that can transmit defined messages without reference to accompanying speech. These may be 'emblems' that have a conventional meaning like thumb up for 'okay' or touching the temple with the extended hand for 'military salute,' or they may be pantomimes of tool use that indicate objects by miming their use. Usually, diagnosis and research on

apraxia concentrate on pantomime of tool use. A practical reason for this preference is that aphasic patients may not understand the verbal label of emblems, whereas comprehension of the name of the tool whose use they should demonstrate can be facilitated by showing the tool or a picture of it. A theoretically more interesting reason for the preference may be that pantomime of tool use is a communicative gesture that is derived from the material interaction with external objects. It thus spans a bridge from instrumental to communicative functions of the hands.

Theoretical accounts of defective pantomime emphasize either its derivation from real tool use or its communalities with the disturbance of verbal communication in aphasia. We will consider both aspects in turn.

Knowledge about how to use a tool is a prerequisite for pantomiming its use, but the conclusion that pantomime is equivalent to running the motor program of real use without holding an implement does not withstand scrutiny. Rather than replicating the motor program of use, pantomime segments the compound image of hand, action, and object into distinctive features of the object and the acting hand that are combined for giving a comprehensible image of the pretended object and its use. For example, when miming to grasp a glass, normal subjects open their hand to the approximate width of the pretended glass at the start of the transport movement and stop the transport at its pretended location without further changing the aperture of their grip (Laimgruber et al., 2005). The width of the aperture demonstrates the width of the glass, and stopping the transport of the hand suffices for indicating the grasp. By contrast, in real grasping, scaling of grip width to the width of the glass is achieved by first opening the hand in proportion to, but wider than, the visually perceived width of the glass and then closing it around the glass. Opening and closing are important for swift and secure grasping but have little value for discrimination of the grasped object. Pantomime may neglect them. Instead, the pantomime must specify features that in actual use are determined by the manipulated object. For example, in real drinking from a glass the distance of the holding hand from the mouth is determined by the contact of the glass with the mouth, but in pantomime a plausible distance must be chosen without external support. Arguably, it is the selection of distinctive features of the tool use action and their combination to a continuous movement of the hand that pose the greatest difficulties for patients with apraxia. Thus, the kinematic features of grasping a glass are the same in patients with apraxia as in normal controls, but their pantomimes omits the opening of the hand that indicates the width of the pretended glass (Laimgruber et al., 2005).

Selection and combination of significant features permit the construction of pantomimes of actions that one has never before executed in reality. For example, most persons are able to pantomime playing a violin or a trumpet, but only a small minority can actually perform the pantomimed action. It is even possible to pantomime actions that are out of the range of human motor competence. For example, rhythmical up and down beat of both arms beside the body will be recognized as a pantomime of flying like a bird. The need to create a gesture rather than to retrieve it ready-made from stored motor programs can also explain the paradoxical finding that aphasic patients have more problems with pantomime of tool use than with the production of emblematic gestures on command, although the verbal comprehension of the instruction is more difficult for emblems than for pantomime (Goodglass and Kaplan, 1963; Buxbaum et al., 2007). In the same vein, we found that in aphasic patients the accuracy of pantomime on command predicts the diversity and comprehensibility of gestures used for compensating the loss of speech when retelling short stories (Hogrefe et al., 2012). The stories did not put any particular emphasis on tool or object use. The most plausible link between success on pantomime and the efficiency of spontaneous gestures is their creation by selection and combination of distinctive features.

The conclusion that apraxic patients' difficulties with pantomime concern its communicative function rather than its descent from actual use leads to the question as to how they relate to accompanying impairments of other communicative channels, notably the impairment of verbal communication in aphasia. Like aphasia, defective pantomime of tool use is, strictly bound to left hemisphere lesions (Goodglass et al., 1963; Goldenberg et al., 2003). About one half to two third of patients with aphasia have problems with pantomime, and the proportion raises to more than 90% when only patients with global aphasia are considered (Goldenberg et al., 2003). Moreover, there is no right-handed patient on record who had apraxia of pantomime without aphasia. The suspicion that aphasia and apraxia are both symptoms of one and the same pervasive destruction of communicative abilities is, however, invalidated by observations of left-handed patients who had apraxia for both imitation and communicative gestures on command but not aphasia following right brain damage (Margolin, 1980; Goldenberg, 2013).

Contrary to widespread belief but in accordance with the sparing of pantomime in visuoimitative apraxia, the crucial lesions for defective pantomime are located in inferior frontal regions and adjacent white matter rather than in parietal regions (Goldenberg et al., 2007).

Tool Use

Defective tool use was the first symptom that received a designation as 'apraxia' (Steinthal, 1871). Liepmann classified defective use of tools and object as 'ideational' apraxia to indicate that the difficulty concerns the planning of the action rather than its motor execution, and later authors mostly adhered to this taxonomy. The uniform designation conceals substantial differences concerning its interpretation. Liepmann owed the description of this variant of apraxia mainly to the Prague psychiatrist Arnold Pick (1905) who described errors of demented patients on everyday multistep actions with multiple objects like dressing or preparing and lighting a pipe. Errors were due to omission or preservation of single steps and to loss of the superordinate goal of action sequences. Liepmann concluded that "ideational apraxia is a mental insufficiency which manifests itself in the domain of action but has its roots in deficits which are not specific for action" (Liepmann, 1929: p. 199). In the modern literature, this variant of apraxia has been rediscovered

independently from the traditional descriptions and has been named 'action disorganization syndrome' (Humphreys and Forde, 1998; Cooper et al., 2005) or 'naturalistic action impairment' (Schwartz et al., 1999). By contrast, the term 'ideational apraxia' is now predominantly used for defective use of single tools that manifests itself also outside of the context of multistep action sequences (Morlaas, 1928; De Renzi and Lucchelli, 1988). As I will outline in the following sections, the two interpretations of 'ideational apraxia' correspond to different variants of deficient tool and object use that have different neural substrates (see **Figure 1**). I will discuss them separately.

Use of Single Tools

Defective use of single familiar tools is the least frequent but most impressive manifestation of apraxia. For example, patients may try to cut bread with the reverse edge of the knife or even with a spoon, may press the head of the hammer upon the nail rather than hitting, or may try to press toothpaste out of a firmly closed tube. It seems that patients have lost their knowledge about the correct use of these familiar tools. Experimental studies reveal that there are at least two sources of such knowledge. One is the storage of 'functional knowledge' in semantic memory. It associates types of tools with their purpose, their recipient, and the action of their use. For example, a screwdriver serves for connecting or disconnecting parts; the recipient of its action is a screw, and the action rotation. Retrieval of such functional knowledge can be probed without requiring the actual use of tools by asking subjects to match pictures of tools with pictures of other tools serving the same purpose or with pictures of the typical recipient of their action.

Functional knowledge can exist only for familiar tools and objects, because acquisition and storage of knowledge about an object makes it familiar. If there are several possible uses of a tool, functional knowledge is likely to assign weightages to them by their relative frequency and familiarity. Consequently, the prototypical use predominates. For example, a screwdriver is registered as being useful for screwing and unscrewing rather than for stabbing. One can, however, use tools in non-prototypical ways and find out possible uses of unfamiliar tools. One can scratch with a screwdriver and screw with a coin. There must be a second source of knowledge about tool use that permits detection of possible uses independently from their storage in semantic memory.

The alternative source of knowledge about tool use can be a direct inference of possible functions from structure. Reasoning based on such inference has been termed 'mechanical problem solving' (Goldenberg and Hagmann, 1998), 'mechanical reasoning' (Hegarty, 2004), or 'technical reasoning' (Osiurak et al., 2009). The elements of mechanical problem solving are not the prototypical functions of entire tools, but the functional compatibilities of their parts (Vaina and Jaulent, 1991). Tools and objects are segmented into functionally significant parts and properties, and combinations of these parts and properties with parts and properties of other tools and objects are used for construction of mechanical chains.

Mechanical problem solving can be probed by confronting patients with novel tools and asking them to find out how to manipulate them or by presenting objects together with an array of tools but without the tool usually employed and asking them to choose the tool that would best complete the task (Heilman et al., 1997). In a variant of this task, Osiurak et al. (2009) presented objects paired with tools that usually are not employed for their use, and asked patients to show how the prototypical action associated with the object could nonetheless be achieved by employing the tool in an unusual way. For example, they presented a pot of yogurt with a fork. Eating of the yogurt could be achieved by turning the fork around and using the handle as a provisional spoon.

In patients with unilateral brain damage, the tests indicate that both, functional association and mechanical problem solving are impaired only after left brain damage (Hartmann et al., 2005), but whereas retrieval of functional knowledge is contingent upon integrity of the middle temporal lobe, mechanical problem solving depends on integrity of parietal regions (Goldenberg and Spatt, 2009). Impressive behavioral dissociations between preservation and disturbance of both components have been demonstrated mainly in patients with bilateral degeneration of either the temporal or the parietal lobes (Sirigu et al., 1991; Hodges et al., 2000; Spatt et al., 2002). In patients with unilateral left-sided lesions, defective use of single familiar tools seems to be bound to large lesions that interrupt both sources of knowledge, but there are indications that insufficient appreciation of functionally significant parts and properties of tools has more impact on the use of familiar tools and objects than disturbed retrieval of functional knowledge (Osiurak et al., 2009; Goldenberg et al., 2009).

Multistep Actions with Multiple Tools and Objects

In daily living, one rarely encounters a situation like in testing for use of single tools where one is handed a tool and asked to perform its prototypical action on an adequately prepared recipient. Typically, the use of the single tool is embedded in a chain of actions involving several tools and objects and aiming at a superordinate goal transgressing and modulating the purposes of each single action step. The need to keep track of completed and outstanding steps of actions, to avoid possible interferences between sequential action steps and to maintain the superordinate goal against digressions create more opportunities for error than the isolated use of single tools. Whereas single tool use by healthy persons is virtually errorless, slips of actions in multistep tasks are a common experience of everyday life, but they rarely attain the severity of errors that are committed by some patients with brain damage.

In contrast to the exclusive association of defective use of single tools with left brain damage, multistep actions are affected also by lesions in the right hemisphere or diffuse brain damage (Schwartz et al., 1998, 1999; Hartmann et al., 2005; Goldenberg et al., 2007). Clinical experience and detailed descriptions of single cases (Poeck and Lehmkuhl, 1980; Rumiati et al., 2001; Forde et al., 2004) suggest more severe aberrations from the normal course of action in patients whose brain damage affects the left hemisphere, but group studies failed to confirm this impression, nor did they show differential effects according to the intrahemispheric localization of lesions (Schwartz et al., 1999; Hartmann et al., 2005; Goldenberg et al., 2007).

The apparently uniform impact of any brain damage on multistep actions reminds of Liepmann's contention that 'ideational apraxia' is a manifestation of 'general mental insufficiency.' In the modern literature, a very similar proposal has been formulated as 'resource limitation.' According to this view, any brain damage limits the resources of attention and effort, and this limitation has a homogenizing effect that obscures any manifestations of underlying specific neuropsychological deficits (Buxbaum et al., 1998). However, some insight into differential mechanisms underlying the superficially uniform impairment of patients with different kinds of lesions has been provided by analyses of correlations between defective multistep actions and accompanying other symptoms of brain damage. In patients with left brain damage and aphasia, severity of impairment on multistep actions correlates with their difficulties with single tool actions and, for some multistep actions also with the severity of aphasia and of semantic memory impairment. Right hemispheric brain-damaged patients have neither aphasia, nor semantic memory impairment, nor problems with single tools. Their errors on multistep actions with multiple objects are correlated with the severity of hemineglect, a tendency to ignore the contralateral half of one's body or of external space (Schwartz et al., 1999; Hartmann et al., 2005). Subsumption of the diversity of accompanying impairments under the umbrella of 'resource limitation' is not very satisfactory. A more convincing assumption would be that there are in fact different mechanisms at work in different patient groups but that the inherent constraints and difficulties of multistep actions with multiple objects restrict the loci and kinds of possible errors and leave little freedom for neuropsychological disorders to manifest themselves in specific and recognizable ways.

Conclusions

Our survey clearly demonstrates that apraxia is not a unitary disorder. It rather appears as a collection of heterogeneous deficits that differ from other motor sequels of hemisphere damage by the bilateralism of their manifestation but have otherwise little in common. However, this bilateralism is not trivial. The deviation from the basic anatomy of motor cortex indicates that problems concern the planning and control rather than the motor execution of actions. It thus points to the cognitive rather than purely motor character of apraxia.

It has been proposed that the intervention of high level cognitive mechanisms comes to the fore most clearly in three core manifestations of apraxia: Imitation of meaningless hand postures, pantomime of tool use, and use of single tools (Goldenberg, 2013). Anatomically, they have in common a strict dependency on left hemisphere lesions. Functionally they have in common that they involve segmentation and combination of elements: For imitation of hand postures, the multiple visual features of the demonstrated gesture are segmented into distinct body parts which are combined to distinct postures. For pantomime of tool use, the compound image of hand, action, and object is segmented into distinctive features of the object and the acting hand, which are combined for giving an understandable image of the pretended object and its use. For use of single tools, the structures of tool and recipient are segmented into functionally significant traits, which are combined to form mechanical chains that transmit manual actions into the effects of the tool upon its recipient.

Segmentation and combination are the essential constituents of generative systems that can create a multitude of entities out of a limited number of elements (Abler, 1989). Their application to motor control enables subjects to understand and reproduce complex actions and to create adaptive actions in response to novel demands. Apraxia interferes with these cognitive contributions to motor control.

Archaeology and Cultural Memory

Abstract

This article discusses several theoretical concepts of how collective memories function in society. An overview is given of the different implications of these concepts for both the archaeological study of ancient sites and objects, and archaeology as an academic discipline in the context of a given society or nation of the present.

Individual humans can remember occurrences of their own lifetimes as well as of a collective past, whether near or far removed in time from the moment of remembering. While the former is restricted to events and processes at which the particular person was physically present as a conscious human being, the latter includes accounts of occurrences happening both before and during an individual's life. Although records of personal memories may be an important aspect in some areas of archaeological research as has been demonstrated, e.g., in the case of twentieth-century archaeology (Burström et al., 2009), most archaeologists are dealing with collective memories.

This article discusses several theoretical models of how collective memories function in society. An overview will be given on the different implications for both the archaeological study of ancient sites and objects and archaeology as an academic discipline in the context of a given society or nation of the present.

Archaeology and Theoretical Approaches to Memory

For the longest time in intellectual history, human memory has been seen as a huge archive in every human being from which, at any point in time, specific items can be retrieved in the process of remembering. This was, for example, the view of Saint Augustine (*Confessions*, X. viii (12)). In this perspective, individuals may create mnemonics in order not to forget on particular occasions (Yates, 1966) and they are able, in principle, to remember past events accurately. Collective memories may work accordingly. More recently, however, it has been argued that the issues involved in remembering and forgetting are not that simple (Cubitt, 2007).

Remembrance as a Social Construction

Remembering, and indeed forgetting, are strongly influenced by circumstances of the time in which they take place. Moreover, memory can fail completely or 'make up' stories or events that allegedly took place in the past. Maurice Halbwachs argued that some key factors affecting memory derive from the social arena that people always inhabit when they remember. Halbwachs introduced the concept of *mémoire collective* (collective memory), and emphasized how strongly social processes influence not only people's personal memories of their own lifetimes, but also a community's shared memories of the past. Collective memories are crucial for the identity of groups such as families, believers of a religion, or social classes (Halbwachs, 1992). Although memories vary between individuals and no two persons share identical 'collective' memories, anyone who has ever lived for some time in a foreign country knows what it means not to share the same collective memories as colleagues and friends. Collective memories can be evoked at particular sites (see below), and they have, in turn, the potential to shape such sites. As an example of the latter, Halbwachs discussed the medieval 'creation' of the Holy Land by the superimposition of an imaginary landscape on Palestine (Halbwachs, 1971).

The collective memory of archaeology provides a topical example. Although little research has been conducted on that topic, it is clear that some historical figures such as J. J. Winckelmann, C. J. Thomsen, H. Carter, and H. Schliemann are considered widely to be among the 'fathers' of the discipline. Similarly, sites such as the Valley of the Kings, Troy, Rome, Pompeii, Stonehenge, Teotihuacan, and Machu Picchu as well as museums such as the Louvre, the British Museum or the Metropolitan Museum of Art are remembered collectively as key sites of archaeology and are now major tourist attractions. While the significance of any of these persons, sites, and museums is not disputed here, today they are inseparably linked with how one collectively remembers the history of archaeology including events that happened long after these individuals were dead, at other places than those mentioned, and concerning artifacts displayed elsewhere. During the nineteenth and twentieth centuries, archaeology became a rich cultural field in which literature, film, tourism, advertising, and even other academic disciplines like psychoanalysis together remembered the spectacular discoveries at famous ancient sites by celebrity archaeologists of the past (Frayling, 1992; Zintzen, 1998).

Going beyond Halbwachs's argument, social scientists have long argued that memory of the past is not only influenced but also constituted by social contexts of the present (Middleton and Edwards, 1990; Zerubavel, 2003). Such reasoning questions the separation of past and present in a fundamental way. It becomes pointless to discuss whether or not a particular remembered event or process corresponds to what 'actually' happened; all that matters are the specific conditions under which such memory is constructed. The distinction between personal and collective memory is thus not necessarily a sharp one. Both reflect, first and foremost, the conditions of the present in which they originate. Individual persons learn collective memories

through socialization, but they retain the freedom to offer alternative views of the past, which may themselves later inform the collective memory. It may eventually become impossible to tell which memory is indeed an accurate remembrance of an occurrence at which a person was present, and which is merely a remembrance of an earlier remembrance that was created by a story read in a book or watched on television (Morris-Suzuki, 2005). As a consequence of such reasoning, the focus of memory studies in the social sciences and to some extent in the humanities has shifted from studies seeking to establish the truthfulness or social constructedness of memory to studies of how particular mnemonic and commemorative practices in past and present contributed to the formation of personal and collective human identities and social strategies and conflicts linked to them (Olick and Robbins, 1998). In archaeology, this trend has become particularly visible in a number of studies of remembrance and commemorative practices in historic and modern societies (Williams, 2003, 2006; Walls and Williams, 2010).

Les Lieux des Mémoire

Pierre Nora edited a monumental work of seven volumes about the loci memoriae of France, entitled *Les lieux des mémoire* (Nora, 1984–92). A *lieu de mémoire* (site of memory) is any significant entity, whether material or nonmaterial in nature, which by dint of human will or the work of time has become a symbolic element of the memorial heritage of any community. Nora deals specifically with sites where modern France constructs its national identity by constructing its past. Crucially, these sites of memory not only include places, such as museums, cathedrals, cemeteries, and memorials, but also concepts and practices, such as generations, mottos, commemorative ceremonies, and objects, e.g., inherited property, monuments, classic texts, and symbols. Archaeological sites of memory discussed in individual contributions include the prehistoric art genre known as palaeolithic cave paintings, megalithic monuments as a set of particular objects, and the concept of the Gauls.

According to Nora, all sites of memory are artificial and deliberately fabricated. Their purpose is to stop time and the work of forgetting, and what they all share is 'a will to remember.' Such sites of memory are not common in all cultures, but a phenomenon of our time; they replace a 'real' and 'true' living memory that was with us for millennia but has now ceased to exist. Nora thus argues that a constructed history replaces true memory. Although Nora's idealization of memory at the expense of history and heritage has now been almost forgotten, the variety of empirical phenomena he considered relevant and invited contributors to study in detail has inspired many others and led to similar projects in other countries (e.g., Francois and Schulze, 2001). Many of the sites and notions addressed are directly relevant to the fields of historical and contemporary archaeology as well as landscape archaeology.

Cultural Memory

Jan Assmann employed the term *kulturelles Gedächtnis* (cultural memory) in a study of the past in ancient Egypt (Assmann, 1992). Cultural memory can be defined as the cultural expressions of a collective memory, including written texts, symbols, monuments, memorials, etc. It is distinct from the 'communicative memory' of individuals' lifetimes, which is expressed by means of direct communication. Cultural and collective memories are 'retrospective.' Correspondingly, the hopes and expectations of people for what will be remembered in the future can be termed 'prospective memory.' Such hopes find their expression not only in the design and 'content' of a site of memory, but also in its monumentality and the durability of the materials employed. If prospective memory is the desired memory when building a site of memory, retrospective memory is how this site is in fact later remembered.

According to Assmann, cultural memory embraces both *Erinnerungskultur* (memory culture) and *Vergangenheitsbezug* (reference to the past). Memory culture is the way a society ensures cultural continuity by preserving, with the help of cultural mnemonics, its collective knowledge from one generation to the next, rendering it possible for later generations to reconstruct their cultural identity and maintain their traditions. Memory culture relies on later references to (mnemonics of) the past. Such references reassure the members of a society of a shared past and collective identity, and supply them with an awareness of their unity and singularity in time and space. Cultural mnemonics, such as preserved ancient monuments or artifacts, trigger recollections of past times, although these can be fabrications rather than accurate representations of the past. Arguably, this second aspect of cultural memory has wider implications. The fact that collective memories of the past occur without being able to ensure cultural continuity suggests that the past can be given specific meanings for reasons other than accurate reconstruction. In effect, as interpretations of the past have changed over time, ancient sites and artifacts have been interpreted quite differently during their long 'life histories' (Holtorf, 2008).

For archaeologists, both actual continuities and various archaistic reinventions or other symbolic references to a rediscovered or recreated past are interesting phenomena to study. Because both already occur widely in antiquity, Nora is arguably misguided in limiting the existence of sites of memory to the modern era. There is ample archaeological evidence for deliberate attempts to stop time and make contemporaries remember by 'artificial' means. Indeed, archaeologists have in recent years devoted much attention to studies in many parts of the world of what has been called 'the past in the past' (Assmann, 1992; Jonker, 1995; Van Dyke and Alcock, 2003; Williams, 2006; Holtorf, 2008).

The Relationship between Archaeology and Collective Memories

Archaeology versus Memory

It has often been assumed that the academic study of the past is superior epistemologically to popular notions of the past, as they are reflected in folklore, myths, or in other expressions of collective memory. Maurice Halbwachs contrasted memory and history as two oppositional ways of dealing with the past. Historians aim at writing a single objective and impartial

universal history, whereas collective memories are numerous, limited in their validity to members of a particular community, subject to manifold social influences, and restricted to the very recent past in scope.

Likewise, Pierre Nora argued that memory and history are two very different phenomena, but his preference was the opposite to that of Halbwachs. Nora distinguished true memory, borne by living societies maintaining their traditions, from artificial history, which is always problematic and incomplete, and represents something that no longer exists. For Nora, history holds nothing desirable. In each case, the term 'history' might be replaced with 'archaeology.'

Archaeology as Memory

Other scholars fundamentally challenged the split between history/archaeology and memory, and proposed instead a more fluid transition (e.g., Burke, 1989). In this view, history and archaeology are seen as special cases of social and cultural memories. Doing archaeology simply means (1) to recognize, and treat, certain things as 'evidence' for the past and (2) to describe and analyze it in a way that is valuable according to the standards of archaeologists. These practices are not categorically different from how people engage with the past in their everyday lives. History and archaeology, like all forms of memory, give particular meanings to ancient sites and artifacts. Some of these 'academic' meanings eventually influence collective memories of the past in the present. But many never leave the sphere of academia, and are short lived there too. What is interesting in studying collective memories of the past, academic or not, is, therefore, not only how truthfully they may represent (some) part of a past reality, but also why particular memories are created and adopted (or not) in particular contexts, and what sort of controversies may arise from them. Topical archaeological examples are provided by Paul Shackel's (2003) discussion of competing present-day memories of American Civil War sites and by Gabriel Moshenska's (2010) analysis of contested memories at specific places associated with the Nazi area in Berlin.

Archaeology and Nationalist Agendas

The history of archaeology provides many examples of the great importance of the past for collective identities of modern nations (Kohl and Fawcett, 1995; Diaz-Andreu, 2007). Archaeology originated as an academic discipline in the nineteenth century – the great age of national Romanticism and the European nation-states. This is no coincidence; archaeology has from its beginnings been directly bound up with politics. At times of fundamental social change, people turn to their 'origins' and seek reassurance either in a 'better' past, or in historical traditions and collective identities that legitimate a radical political movement or new social order. This was the situation in early nineteenth-century Europe in the aftermath of the social changes brought about by the French Revolution. By projecting backward contemporary collective identities and establishing (or even inventing) the origins of their respective national people in the distant past, the young European nations reassured their citizens of a shared history, and thus a common identity, legitimizing their existence in the present. As a result, archaeology became institutionalized in the form of national museums, professorships at universities, and legislation protecting the archaeological heritage. A case in point are the defenses of Masada in Palestine, which fell to the Romans after several years of Jewish resistance in AD 73, but not until the last defenders had committed collective suicide. They were not rediscovered as a prime object of Jewish collective memory until the 1920s coinciding with the rise of Zionism (Schwartz et al., 1986).

Since the nineteenth century, a lot of archaeological research has been adopting a 'culture-historical' approach, investing much effort in the ethnic interpretation of material evidence according to which clearly defined types of sites and artifacts regularly recurring together were associated with particular ethnic cultures corresponding to modern cultures. Outside of Europe, colonial and imperialistic archaeologies attempted to establish similar ways of conducting archaeology. The ultimate aim was the establishment of cultural sequences connecting present-day societies with their distant origins in a more or less direct line of historic continuity. In extreme cases, as in Nazi-Germany 1933–45, such reasoning could ultimately lead to aggressive territorial claims when archaeological finds in neighboring countries were seen as connected with archaeological cultures in contemporary Germany. Today, some 'first nations' of indigenous populations in North America also use ancient sites and finds to establish collective identities and legitimize territorial claims.

The connection between archaeology and modern nations is still visible at the beginning of the twenty-first century in many 'national museums' of archaeology, in national academic journals with titles such as *Germania* and *Gallia*, and in the key role of the national pasts in both teaching curricula and popular culture. During the last decade of the twentieth century, and with the emergence of new nation-states in the former Yugoslavia and the former Soviet Union, similar processes were repeated (Kohl and Fawcett, 1995). Although in postwar Germany, remembrance of the Nazi past, e.g., at the sites of former concentration camps, has been rendering national memories into something that is deeply problematic and troubling, in other countries, collective memories may still support nationalist ideologies effectively, while contradicting results gained from archaeological research. Some archaeologists may lend their authority to support such ideologies. At first, this appears to raise a dilemma for those archaeologists who are prepared to accept the equal legitimacy and value of all collective memories of the past, whether created by academic archaeology or other groups; either they have to accept all constructions of the past as legitimate alternatives to their own accounts, or they would contradict themselves by dismissing some as false. A realistic solution is to accept many alternative collective memories of the past as manifestations of particular needs and desires in present-day contexts, but be prepared to fight some of them on political or other grounds, and publicize widely any dangerous consequences or implications. Such issues have recently come to the fore in several regions of the world. They demonstrate that archaeology and the politics of collective/national memory are deeply intertwined and ultimately interdependent. Instead of arguments about theoretical principles, future archaeologists will be challenged increasingly to find

pragmatic guidelines as to how to behave and act in politically highly charged situations.

Abstract

Most people do not think of archaeology as political, but issues focused on the repatriation of human remains and sacred objects have made archaeology a very political discipline. Repatriation of human remains and sacred objects has become a focus of concern in the United States, Canada, Australia, and other countries over the last 20 years. This article examines the definitions and nature of repatriation, the history of repatriation laws and approaches, the politics of the issues, international vs US laws, key issues and foci of current debate, and potential future issues associated with repatriation. There has been a marked culture change among archaeologists and museums concerning these issues, and this shift will have a lasting impact on archaeology, on indigenous peoples, and on the nature of museums. Archaeology can no longer claim to exist outside politics.

Introduction

Archaeology has not traditionally been seen as a political discipline. Most of the complexities associated with 'doing' archaeology focus on whether or not a particular archaeologist has received the appropriate permits, is conducting fieldwork properly, understands and analyzes the cultural materials, and publishes findings. However, there are political issues associated with archaeology, particularly in relation to cultural resources management work, in which archaeologists must mitigate the impact of development and construction on archaeological resources. Archaeology is also not immune to infighting and other types of academic jockeying for positions, but on the whole, the discipline has not been the focus of major political battles. Any apolitical view of archaeology changed in the mid-1980s and early 1990s when the issue of repatriation of human remains and sacred objects became hotly contested by Native Americans. Archaeology was suddenly in the news for topics other than new things found, and archaeologists were not cast as the 'good guys.' Eventually, many states and countries passed legislation concerning human remains and sacred objects, and the two laws that were the leads in this trend were the National Museum of the American Indian Act (NMAIA; 20 United States Code (U.S.C.) 80q et seq.) and the Native American Graves Protection and Repatriation Act (NAGPRA; 25 U.S.C. 3001 et seq.)

A focus on repatriation is appropriate and relevant within an article on the politics of archaeology since there have been no other laws or developments within the last 30 years that have had as major an impact on the discipline.

For most members of the general public in the United States (and some other parts of the world), repatriation or reburial (as applied to Anthropology and museums) appears to be a straightforward notion – tribes and/or other appropriate indigenous groups or relatives ask for the return of one or more objects or human remains that are historically or culturally related to the group, and the museum or university gives it back, or should give it back. Some are aware that the process can be a bit more complicated, but most people have little idea of the nature and process of repatriation, or the problems and complications that are associated. This is not to say that repatriation is problematic and should not be done, but rather that all parties are obligated to follow an explicit legal process. However, the biggest differences between repatriation in the twenty-first century and repatriation in the twentieth century are: (1) repatriation of human remains and associated objects is now law in the United States and some other countries of the world, and (2) repatriation of human remains (in particular) is now widely accepted as something that responsible and ethical institutions do.

Definition

The dictionary definition of 'repatriation' is: "send (someone) back to their own country, or send or bring back to one's own country." Wikipedia defines repatriation similarly:

> Repatriation (from Late Latin *repatriare*) is the process of returning a person back to one's place of origin or citizenship. This includes the process of returning refugees or soldiers to their place of origin following a war. The term may also refer to the process of converting a foreign currency into the currency of one's own country.

The repatriation and reburial of human remains, funerary and sacred objects is a special case of repatriation. Groups representing indigenous peoples around the world have requested that human remains and sacred objects originally taken from their respective historical territories be repatriated from museums and other institutions. Sometimes institutions repatriate human remains and items because they agree that they should rightfully be in the possession of the group that is descended from them, other times the return is based on the requirements of specific laws.

One reason that repatriation – as applied to archaeology and physical anthropology – is not a simple process is because the motivation for these requests is about people in the present and their perception of the past in the present. Repatriation claims are often associated with politics, ethnic identity, and other debates or problems in contemporary society that have or claim to have a historical link to the object or human remains. Such motivations do not make the claim less valid or less appropriate, but the context of the request can be important to understanding the request. Archaeologists, physical

anthropologists, and museum directors do not generally approach repatriation from this perspective; they try to contextualize the materials based on archaeological and historical knowledge and science. It is a discussion that has often led to misunderstandings and differences because the parties are focused on different matters. However, since repatriation laws have come into effect, it is a discussion that is happening in many places, and consequently museums are getting better at responding to requests, and indigenous groups are getting better at making their requests. Repatriation is most active in the United States, primarily because repatriation laws have been in effect for the longest period of time.

Please note that although the term 'archaeologist' is generally used in this article, the reader should understand that this is a shorthand or simplified way of encompassing people who are archaeologists, physical anthropologists, human osteologists, museum studies scholars, and those in related fields who deal with human remains, grave goods, and sacred or religious objects. Furthermore, archaeology has historically taken the lead in these discussions about repatriation, so this shorthand approach is reasonably accurate as well. Archaeologists have most consistently found themselves in the center of the political debate.

Historical Background

During the 1960s, 1970s, and 1980s, some US institutions listened and responded to repatriation requests from tribes, subsequently returning human remains and sacred objects before specific laws were in place. However, there is no question that the passage of two federal laws in the United States – NMAIA (20 United States Code (U.S.C.) 80q et seq.) and the NAGPRA (25 U.S.C. 3001 et seq.) – dramatically changed the nature and process of repatriation. There is no doubt that the effect of this change in process and change in culture has had international implications.

Buikstra (2006), Lambert (2012), Mihesuah (2000), Trope and Echo-Hawk (1992), and Ubelaker and Grant (1989) provide detailed discussions of the history and some of the problems of repatriation in the United States. During the 1980s, the position held by many institutions, as well as by many national professional organizations, was that the ethics of today supersede those of the past, and museums should consider how to change accordingly. At the basic level, repatriation should be done for living descendants upon request and examination of the claim. As Ubelaker and Grant (1989) note, if a group requested remains where there were no living descendants, that group must demonstrate compelling religious or cultural values that outweigh scientific interests. This position also reflected the position of the Society for American Archaeology (SAA) at the time. However, the SAA increasingly assumed the role of representing the scientific community during the 1980s and their view broadened to some degree.

Since the 1980s, the SAA has been remarkably consistent in their position on repatriation (Lovis et al., 2004). The SAA argued for repatriation, but on a case-by-case basis. Indeed, the SAA Executive Committee passed an initial resolution in 1983, followed by a revised version in 1986, and a reaffirmed position in 1999. The key points of the SAA position include: (1) both native and scientific viewpoints have legitimacy; (2) scientific importance must be considered against the strength of affiliation; (3) implementation of repatriation should be done on a case-by-case basis because of the variability in circumstances and histories; and (4) communication and consultation with affected groups is of critical importance. Since 1986, the SAA (Lovis et al., 2004) has recognized the importance and legitimacy of repatriation, and worked actively with Congress to create balanced legislation. Note, however, that not all tribes welcomed the SAA position.

Some native tribes and organizations, archaeologists, and other activists argued that repatriation represented something that was morally and ethically important for the archaeological profession to do, even if archaeology lost access to the remains and artifacts. However, even though several states enacted legislation that in some manner dictated repatriation and/or consultation with native groups, there was no consistent national policy until the 1990s.

During the late 1980s, a number of tribes in the United States argued that repatriation of human remains was a human rights issue – that these were human bodies that had to be treated with respect and respect was not possible if the remains were excavated and placed in a museum. Tribes did not see much difference between archaeologists and looters. One incident that angered many (including many archaeologists) happened in Iowa. A cemetery area was excavated due to road construction. All of the historic white settlers were immediately moved to a new location where they were reburied, and the Native American remains were sent to a museum. The lack of consistency and parity, and the continuing idea that Native American remains belong in a museum (in part suggesting that this may be because they have no clear descendants) represented the perfect example of what was wrong with archaeology and museums. Ironically, it is likely that in the Iowa case, if archaeologists and physical anthropologists had their way, they would have treated all remains the same, but would have studied them all before reburying.

A number of issues and events changed archaeological and other perspectives on repatriation. First, there were several instances, like the aforementioned Iowa case, that led many archaeologists to become increasingly uncomfortable over the idea of study and curation. In the 1980s and early 1990s, the archaeologist who perhaps best personified this position was Larry Zimmerman. In one article, Zimmerman reflects on his experiences and the present and future of archaeology (2000). Zimmerman notes (2000: pp. 294–295) that the reburial issue's trajectory has followed classic syncretism, or a coalescing or reconciliation of differing beliefs. Zimmerman (2000: p. 295) argues that "the problem has been that the belief system of Western science about the past, through archaeology, had imposed itself on belief systems of indigenous peoples about their pasts and those they consider their ancestors." Because archaeologists had little resistance from these indigenous people over a long period of time, they assumed that these people agreed or did not object. The past 25–30 years has demonstrated that archaeologists were wrong. Public discussion – as represented in various polls and forums – demonstrates that the general public supported the Native American position.

As Buikstra (2006: pp. 395–396) points out, another influence on the relationships between archaeologists and indigenous peoples was the development and impact of post-processual theories in archaeology in the 1980s and 1990s. This approach to archaeology moved away from being scientific, and was humanistic and contextual in nature, with practitioners arguing for multivocality in interpreting the past (cf Hodder, 1985; Shanks and Tilley, 1987). Such an approach was certainly more open and welcoming to resolving repatriation disputes, but not everyone agreed with the approach or the benefit for repatriation.

The first US law that directly addressed issues of repatriation was the NMAIA (20 United States Code (U.S.C.) 80q et seq.), which was signed into law on 28 November 1989. The NMAIA was written and passed primarily to establish a new national museum dedicated to the history, music, and art of American Native cultures. The collections of the private Heye Foundation in New York formed the basis of this new museum, to be part of the Smithsonian and built on the national mall in Washington, DC.

The new museum opened in 2004. As a part of the new law, Native Americans had lobbied for a Smithsonian repatriation requirement to be included. In particular, the law affects all collections of American Native human remains and funerary items held by the Smithsonian Institution (although the vast majority of relevant human remains and funerary objects are in the Smithsonian Museum of Natural History, the law affects all of the Smithsonian museums, including the new Museum of the American Indian, American History Museum, etc.). The NMAIA dictates that all designated items are to be inventoried and, where possible, the Smithsonian will determine tribal or descendant origins. When the law was passed, the Smithsonian was estimated to have 19 250 sets of Native American remains (Smithsonian Repatriation Office, 2012). As of 31 December 2010, approximately 29% of this number have been offered for return, and about 20% of the total have actually been repatriated (estimated from Smithsonian Repatriation Office's website: http://anthropology.si.edu/repatriation/faq/index.htm).

Lambert (2012: p. 21) makes the point that the NMAIA marks a real "shift in archaeology law from the protection of archaeological resources to the legal acknowledgement of private ownership (or rights of stewardship) by a sector of the American population of a component of the archaeological record."

Legal representatives of appropriate tribes or descendants can request the return of remains and objects. The Smithsonian notifies tribes if they determine an affiliation, but tribes are also encouraged to submit a request for remains to be returned. If there is a disagreement between the Smithsonian and the requesting tribe, the Smithsonian Repatriation Review Committee can examine the case in detail and submit its recommendations to the head of the Smithsonian. The Review Committee is composed of archaeologists, physical anthropologists, tribal representatives, and tribal elders. The tribal representatives on the Committee have one more representative (and therefore one more vote) than the scientific representatives.

One of the most important results of the Smithsonian act is that systematic study of human remains and objects prior to return is a priority, and the law provides funding for a Repatriation Office. As noted by Killion and Molloy (2000), as well as by Ousley et al. (2005), an enormous amount of contextual knowledge and a systematic catalogue have been gained as a result of this law (Smithsonian Repatriation Office, 2012). Data recovered can be used in the future, and data recording has been done in a consistent manner. It is important to realize, however, that the NMAIA *only* affects collections held by the Smithsonian.

The NAGPRA was passed on 16 November 1990 (NAGPRA; 25 U.S.C. 3001 et seq.). NAGPRA is a far-reaching law that was crafted as a compromise between Congress, Native Americans, and the scientific community. Note that although NAGPRA does not apply to the Smithsonian, the Smithsonian has generally accepted and incorporated the regulations of NAGPRA, and the NMAIA was amended in 1996 to reflect this incorporation of NAGPRA regulations.

NAGPRA has several components:

1. It applies to federally recognized Native American tribes, as well as native Hawaiian organizations and Alaska native corporations.
2. In addition to human remains, NAGPRA includes the repatriation of associated and unassociated funerary objects (objects clearly part of a burial as well as objects that were likely funerary objects but for which details are unknown), sacred objects (objects required for rituals and ceremonies), and objects of cultural patrimony (objects that are owned by the group and cannot be owned or sold by an individual).
3. NAGPRA requires museums and federal agencies to identify and inventory human remains and associated funerary objects, and also produce a summary of unassociated funerary objects, sacred objects, and items of cultural patrimony by 16 November 1995. These inventories and summaries were distributed to the federal government as well as appropriate tribes.
4. NAGPRA established tribal ownership of Native American remains and cultural items recovered from federal and tribal lands after 1990, requiring procedures prior to excavating on such land whether the excavations were inadvertent or intentional.
5. Violation of NAGPRA includes prohibitions against trafficking, sanctions against museums for not meeting deadlines and procedures, and enforcement of the Act by the ability to go to court.

NAGPRA established a Review Committee similar in composition to the Smithsonian's Repatriation Review Committee, with the balance tilted toward Native Americans. NAGPRA also established some grants to museums, Indian tribes, and native Hawaiian organizations (although these funds have been very small relative to the need), and the law promulgated regulations to make the law work.

As Lambert (2012: p. 20) notes:

> These laws reveal significant changes in attitudes concerning the scientific value of archaeological human remains over the course of the 20th century, and illustrate the complexities that can arise when secular and religious ethics collide in the conduct of scientific research.

NAGPRA is important – its passage meant that the Federal government was acknowledging that some things in museums were not obtained in a way consistent with modern American ethics, even though the original acquisition may have been legal at the time. Fortunately, NAGPRA was also a legal impetus for beginning conversations between tribes and the scientific and museum communities. Some tribes and archaeologists had already been talking with each other, but NAGPRA mandated such discussions. As Lambert (2012: p. 22) notes: "In light of the history of disenfranchisement of indigenous people in North America, … NAGPRA's passage was an ethical victory that could be shared by all communities impacted by the law."

Key Issues and Current Debate

Archaeologists and museums operating in the United States today adhere to federal laws and policies concerning repatriation. While some were opposed to these laws initially, they now honor the law. More importantly, there has been a significant culture change among the public and among archaeologists and museum professionals, who accept that repatriation is appropriate federal policy. It is important not to minimize this culture change: repatriation is now considered the *de facto* result of most burial excavation in the United States.

Under NAGPRA and the NMAIA, repatriation does not have a timetable. Except for specific dates by which museums were required to report their holdings, there is no deadline for the time when repatriations must be completed. This was done deliberately since it was impossible to estimate how long this process would take, and no one wanted to put the burden of a timetable on tribes who were already overwhelmed by the numbers of potentially related remains and artifacts in museums.

A key issue in the passage of NAGPRA was the concept of 'cultural affiliation.' Cultural affiliation is the basis for decisions about which remains are open to repatriation claims. NAGRPA's definition is "a relationship of shared group identity which can be reasonably traced historically or prehistorically between a present day Indian tribe or Native Hawaiian organization and an identifiable earlier group" (25 USC 3001, Sec. 2[2]). If there is no clear evidence for such a relationship, NAGPRA specifies establishing cultural affiliation based on a "preponderance of the evidence based upon geographical, kinship, biological, archaeological, anthropological, linguistic, folkloric, oral traditional, historical, or other relevant information or expert opinion" (25 U.S.C. 3005, Sec. 7[4]). It is important to understand that preponderance of evidence is a low legal threshold of simply >50%, and all types of evidence are to be treated equally. The notion of cultural affiliation has been problematic in some cases and is the basis for a number of legal and ethical debates about the meaning and intent of the law.

Many in the public think that the so-called Kennewick Man case legally settled the issue of cultural affiliation, but this is not the case (Thomas, 2000). Kennewick Man (found in Washington state) was a legal battle over a very ancient skeleton. A group of scientists and a group of citizens (Friends of America's Past) were on one side, and five Native American tribes and bands from the Columbia River Basin were on the other side (although technically the case was against the United States). Not only did the skeleton date to a very early time, some physical anthropologists argued that the skeleton had characteristics that were more European than Native American in nature. The details of the case can be found in Thomas (2000) and elsewhere. Unfortunately, instead of deciding the case on the basis of cultural affiliation – a finding that might have helped clarify decisions made under NAGPRA – the US Court of Appeals for the Ninth Circuit argued that the Federal Government had failed to prove that the skeleton was Native American and therefore it was not subject to NAGPRA. It was a decision that angered Native Americans and also angered many archaeologists because the decision was based on an idea about which Native Americans and archaeologists generally do *not* disagree – both sides would say that ancient remains found in the United States can generally be considered Native American.

Subsequent to the Kennewick decision, various attempts were made to amend and/or adapt NAGPRA. Most importantly for the present discussion was the Department of the Interior's 2007 decision to address the issue of 'culturally unidentifiable human remains' (CUHR). This category includes the largest majority of archaeological human remains in the United States. Included are those remains that museums and federal repositories have not been able to affiliate with a modern Native American tribe or descendant. Following the lines of evidence provided in the definition of 'cultural affiliation' (and outlined earlier), these are remains for which institutions have not been able to assign an affiliation. For the most part, these remains are those of greater antiquity, with fewer ties to the present. Members of the scientific and museum communities had worried about this group of remains from the very earliest repatriation discussions because archaeologists and museums were concerned about the impact of repatriation law on the study of prehistory. Some Native American groups were also concerned about the rule from both practical and legal perspectives.

The final rule for CUHR was enacted in May 2010. The original negotiations involved in crafting NAGPRA had carefully maintained a balance between various interests. The new rule ignores that balance and favors native issues over any scientific interests or concerns; it also does not necessarily give tribes much leeway in how they wish to respond to repatriation. It is likely that this rule will be the focus of future legal challenges.

One issue in the final CUHR rule focuses on the term 'disposition,' or the outcome of a repatriation claim. NAGPRA does not mandate the nature or type of disposition for successful repatriation claims, intentionally avoiding use of the term 'reburial.' The reason for this avoidance is that any particular tribe might or might not wish a particular or mandated outcome. While most tribes would likely wish reburial, if the repatriation decision is that the remains belong to the group, the specifics of the final disposition should also be the group's prerogative. The CUHR Final Rule effectively calls for the reburial of all Native American human remains currently in museums and federal repositories, even if evidence for any relationship of shared group identity is lacking.

Although many contentious issues remain, current debate in archaeology has moved from the question of whether or not

repatriation is right or wrong, to more complicated issues. Colwell-Chanthaphonh and Ferguson (2006) present one aspect of this new direction. Instead of principles and rules of ethics, they promote the idea of Virtue Ethics. "Instead of beginning with questions of obligations and oughts, Virtue Ethics begins with questions of character, focusing on relationships and the subjectivities of social interaction" (Colwell-Chanthaphonh and Ferguson, 2006: p. 118). They argue that we need to focus on agents and sustained actions, rather than single acts. Effectively, Colwell-Chanthaphonh and Ferguson (2006) argue for a more complex, layered discussion about archaeological practice. They note that archaeologists have a series of unique relationships with multiple interactions, and these interactions have consequences for ethical standpoints.

International Perspectives

In their broad discussion of ethics of bioarchaeology, Larsen and Walker (2004: p. 114) outline three ethical principles for the study of human remains, whether in the United States or internationally: (1) human remains should be treated with dignity and respect; (2) descendants should have the authority to control the disposition of their relatives' remains; and (3) because of the importance of human remains for the understanding of our common past, human remains need to be preserved when possible so that they are available for scientific research. From the discussions earlier, it is clear that there may not be universal agreement on these principles.

Canada and Australia share with the United States a basic issue associated with repatriation: the majority of the contested collections derive from minority indigenous populations where treatment of the dead is an important part of broader indigenous rights issues. Most repatriation efforts focus on trying to redress historical wrongs associated with Western colonialism (see DeLeiuen's discussion and summary of the Australian situation in this volume).

Buikstra (2006: pp. 408–409) notes that Canada has no federal legislation similar to NAGPRA, but relationships between First Nations and archaeologists are strong. Why the difference between countries? First, the Canadian archaeological profession voiced their sympathy with First Nation concerns relatively early, with physical anthropologists practicing *in situ* analyses and reburials during the 1970s. In other words, Canadian bioarchaeologists were collaborating and consulting with First Nations over a decade before US archaeologists, and they did so without being mandated by legislation, producing impressive work with multivocal perspectives. Interestingly, there are multiple examples of First Nations requesting osteological analyses, and allowing destructive tests. The National Museum of Canada stopped accessioning human remains in the early 1970s. As Buikstra (2006: p. 412) notes, "Canadian museums, physical anthropologists, and archaeologists appear to favor mediation over litigation in addressing repatriation issues."

Lambert (2012: pp. 25–26) notes that while the United States, Canada, and Australia have seen repatriation on a national scale coming from indigenous populations and issues relating to colonialism, some similar historical situations exist in Argentina, Norway, and South Africa. However, to date, repatriation efforts in these countries have been limited, and generally involve the return of named, historically significant individuals. Recent developments indicate that laws and policies similar to those in the United States are likely.

In Israel (Nagar, 2011: p. 8), opposition to the excavation of human remains is associated with sites dating to Classical Antiquity and comes from a group of extremist religious Jews who believe that graves of Jewish dead should always remain undisturbed; their political power has been successful in gaining some severe restraints on research. Nonetheless, the Israeli Antiquity Authority created and has maintained a human osteological database since 1994; all time periods are included (Nagar, 2011).

In Great Britain, considerable dialogue has focused on repatriation and is in part the result of connections to developments in Canada, Australia, and the United States. However, Parker Pearson et al. (2011) provide a recent summary of the issues and concerns. In 2008, "the British government announced that all human remains archaeologically excavated in England and Wales should be reburied after a 2-year period of scientific analysis" (Parker Pearson et al., 2011: p. 1). Not surprisingly, this announcement caused great consternation on the part of museums and archaeologists. As of the moment, it appears that the policy will not be implemented as stated, but Parker Pearson et al. (2011: p. 3) point out that

> The weaknesses and contradictions in the legal frameworks that govern archaeology are shocking in many respects, and cannot remain unresolved; archaeologists are pulled hither and thither by property law and planning law, while human remains exist in a peculiar (but ethically and morally appropriate) legal limbo in that they cannot technically be owned.

In sum, outside of Canada and Australia, laws regarding repatriation and reburial are scattered and sometimes under debate; they resemble the issues raised for the United States when there is a similar historical colonial situation. Whether or not the twenty-first century sees an increase in repatriation and reburial remains to be seen.

Future Directions

Larsen and Walker (2004) discuss the ethics of bioarchaeology and their view of the future. They argue that compromise is the key to reaching an ethical solution to skeletal studies of ancient ancestors. Compromise can be legislated, as it originally was for NAGPRA, or it can come about through working together. However, Larsen and Walker (2004: p. 118) note that this balance achieved through compromise is now endangered with "a perceptible shift in the balance of power toward extremist native perspectives on repatriation." They close their discussion with the comment that "compromise is developed when there is trust between two parties who have invested time and effort in reaching solutions that may not be perfect, but nonetheless attempt to [address] competing interests of different groups" (Larsen and Walker, 2004: p. 118).

An excellent example of a historic cemetery study that was inclusive from the beginning to the end of the project is the Tucson (Arizona) Alameda-Stone cemetery (Heilen, 2012). The planned building of a new court complex in downtown Tucson required the discovery and removal of a very large historic (1860–80) multiethnic cemetery. Although the project requirements were outlined by a court order, the project was successful because of transparency of the work to the affected parties, and the development of relationships between the various parties. The project developed community-sensitive methods for identifying cultural affinities, as well as addressing a variety of community concerns and requirements. The cemetery included Native American, Hispanic, European, and various other groups, all of whom were involved in the excavation, analysis, and reburial of the remains and artifacts.

The notion of trust is an important one, and will continue to be so in the future, both in the United States and internationally. As noted earlier, Colwell-Chanthaphonh and Ferguson (2006) use the concept of Virtue Ethics to look to the future without specific reference to NAGPRA. They also discuss the concept of trust, and the nature of trust in archaeological practice. They draw on the work of Baier (1994) to outline and discuss 'virtue ethics,' citing Baier's contention that goodwill is an essential component of trust. Colwell-Chanthaphonh and Ferguson (2006: pp. 122–124) outline the complex web of categories of trust relationships in archaeological practice, noting that there are not only relationships within categories, but also relationships between them. Trust requires goodwill, but each group has to interpret acts of goodwill as benevolent (Colwell-Chanthaphonh and Ferguson (2006: p. 127). If we wish to develop trust between archaeologists and museums and indigenous groups, all parties must move to a focus on people and actions over time, rather than things and single interactions at one time. Although it takes time to develop and establish trust, the goal has an excellent reward.

Abstract

Archaeology and philosophy share a long history of engagement. This engagement was most pronounced in the 1960s and 1970s with the so-called New Archaeology that drew upon philosophy of science to build an epistemological and methodological framework. The ensuing debates concerning how to adequately do this resulted in archaeologists being largely disaffected with philosophy of science. In the 1980s and 1990s, while philosophy of science shifted toward a more practice-based post-positivist philosophy, increasingly merging with the interdisciplinary field of science studies, archaeology began to engage with a wider suite of philosophies, including continental and pragmatist sources. Currently, rather than epistemic issues, archaeology and science studies share a growing interest in ontology and the role of materiality in human life.

Archaeology is a dirt-driven enterprise. Despite appearances and certain clichés aside, it is also philosophically sophisticated. In part, this is due to the long history of engagement between archaeology and philosophy. This interaction was most pronounced during the ascendancy in the 1960s and 1970s of what was self-described as the New Archaeology. A legacy of the New Archaeology is the continued association of philosophy in archaeology with a particular set of issues. These issues center upon the scientific nature of archaeology and the type of philosophy involved is, appropriately enough, the philosophy of science. While this was an especially influential period of mutual interaction between the fields, the effects of which continue to reverberate through archaeology, this is only a portion of the history. Recent developments, both within philosophy of science and in archaeology's approach to philosophy more broadly, have considerably altered how the fields engage. There is increasing importance of the interdisciplinary field of science studies and a broader range of philosophies that archaeologists find useful.

In this contribution, I sketch archaeology and philosophy's history of engagement, emphasizing the legacy that explicit epistemological questioning continues to have upon archaeologists' attitude toward philosophy. I discuss the proliferation of 'styles of reasoning' in archaeology, contributing to many camps operating somewhat autonomously within research traditions. I relate this trend to philosophy of science's turn to practice-based reasoning and its increased identification with science studies. I note the broader, more eclectic range of philosophies used by archaeologists, including continental and pragmatist sources. I conclude with discussions of ontology, as opposed to epistemology, that are increasingly encountered in science studies and archaeology and the wider emphasis across the social sciences and humanities upon the material dimensions of life.

History of Engagement

Antiquarianism and Early Calls for Science

There has been a long history of explicit engagement between the fields of archaeology and philosophy. As with other sciences to emerge from the antiquarianism of the eighteenth and nineteenth centuries, the discipline's earliest practitioners were Renaissance men like John Aubrey or Walter Scott who were well versed in the philosophical writings of the day. By the late nineteenth century, archaeology increasingly distinguished itself from the supposed dilettantism of this earlier natural philosophy. Eager to develop their field as a scientific enterprise, archaeologists at the turn of the twentieth century drew upon discussions concerning hypothesis testing and the use of the scientific method in other, more mature sciences like geology. From then on, archaeology experienced philosophical crises roughly every 20–30 years (Wylie, 2002). During these introspective periods, engagement with philosophical sources and debate within archaeology over scientific procedures and reasoning become more visible.

Around World War I, Roland Dixon (1913) and Clark Wissler (1917) published works advocating a more systematic and problem-oriented form of artifact collection. As Wylie (in Rathje et al., 2012) notes, it was hoped that this promotion of scientific reasoning would move the discipline from artifact and data collection for its own sake, a practice associated with antiquarianism, toward a 'real, new archaeology,' as Wissler called it (1917). Despite these discussions, data collection remained the *modus operandi* of archaeology during this culture-historical period in archeology. Disparagingly branded as narrow empiricism by later archaeologists, this period of data amassment and systematization could be approvingly characterized as epistemologically cautious, that is, a period when scholars did not draw conclusions that were unsupported by their data. Nonetheless, dissatisfaction with the interpretive timidity of culture-historians reemerged in the 1930s. These critics, such as Clyde Kluckhohn (1939) and Walter Taylor (1948), drew upon a range of philosophical literature to insist upon the need to build up a body of theory in order to provide explanations for the growing corpus of archaeological data. In Kluckhohn's opinion, archaeologists had barely progressed beyond antiquarian collecting. What was needed was a theoretical framework that posed questions and guided the recovery of relevant data.

A wider, trans-Atlantic set of debates developed in the 1940s and 1950s. These debates continued the previous disagreements over the role of theory in archaeology. They were much farther reaching, however, questioning the function and

veracity of typologies and the nature of the relationship of archaeologist to the archaeological record. These have come to be regarded as the typology debates. Essentially, the dilemma was as follows: were typological schemes, which archaeologists developed based upon formal variations of artifacts, directly indicative of inherent past culture traits, or did such schemes reflect the heuristic purposes of archaeologists? Within philosophy this resembles the nominalism versus conceptual realism controversy. The various responses within archaeology to this perennial problem were situated along a spectrum polarized by Ford's (1954) constructivism and Spaulding's (1953) common-sense objectivism. Constructivism, much like philosophical nominalism, embraced what would later be explicitly formulated as the theory-ladenness, or the impossibility of completely separating theory from data, of archaeological explanation. It describes the typological schemes that archaeologists deploy as tools for imposing order on what would otherwise be indistinguishable material. Archaeologists, interested in certain questions, inevitably impose a subjective ordering on the continuum of artifact assemblages. For the constructivists, such orderings could not be tested against the reality of the archaeological record.

Against this subjectivist position, and holding much in common with conceptual realism in philosophy, the objective stance viewed the categorization by archaeologists as a process of making manifest, or discovering, what was inherent in the record. These scholars rejected this version of theory-ladenness, or the supposed subjective ordering on the part of archaeologists, and adhered to a relationship of independence between the observer (archaeologist) and the real world (archaeological record). This latter position found resonance with the influential logical positivist philosophers of science of the time (e.g., Carnap, 1947). While the dilemma was often cast in the form of a polarity, the majority of archaeologists opted for a middle ground between the two positions. Such a middle position seemed to offer a workable solution, allowing archaeologists to get back to business and create the typologies so central to the operation of the discipline without accepting either relativism, the outcome of a subjectivist approach, or naïve empiricism, the outcome of an objectivist approach (*see* Cultural Relativism, Anthropology of). The general pattern of archaeologists bolstering polarizing epistemic positions with philosophical resources and then settling upon a workable middle ground will be encountered again.

The New Archaeology and Philosophy of Science

In the 1960s and 1970s, philosophy of science was drawn upon to support the theoretical and methodological development of a 'new' archaeology. This time Carl Hempel's (1965) logical empiricism, a modified version of positivism, was imported by outspoken archaeologists, most notably Lewis Binford. While many of the themes encountered in previous periods of contact with philosophy were the same, such as the explicit goal of establishing criteria for the scientific formulation and evaluation of research questions, the New Archaeology represented an especially sustained engagement. It also drew in the participation of more archaeologists and, eventually, philosophers of science. At first there was a fairly direct importation of Hempel's ideas concerning covering-law (C-L) explanation. Modeled upon physics, which was considered to be the paragon of scientific method and reasoning, Hempel nonetheless felt that other, 'softer' disciplines could equally generate universal laws applicable across time and cultures.

Archaeologists such as Binford were keenly aware of the discipline's inability to directly observe its subject matter: namely past societies. However, the natural sciences, like physics, routinely produce generalizations concerning indirectly observed phenomena through the use of mediating instruments of measurement and observation. By adopting a Hempelian epistemological framework, New Archaeologists reasoned that the discipline could equally develop a body of law-like generalizations through the mediating aid of middle-range theory (MRT). It was hoped that MRT would serve as a tool permitting archaeologists to observe past dynamic societies in the static archaeological record (*see* Archaeology, Theory in). Explanation of the archaeological record would be according to Hempel's C-L model. Under the C-L model, particular facets of the archaeological record could be sufficiently explained by fitting or subsuming the data to the body of law-like correlations established by MRT. This would move archaeological reasoning from induction, or amassing enough data until patterns emerge to suggest explanations, to deduction. Deductive reasoning inverts this equation by beginning with hypotheses pertaining to proposed laws, and then systematically searching for data relevant to the empirical implications of such proposed laws. Relevant data meant that it could potentially either support or refute the hypotheses. This was the basic workflow to Hempel's hypothetico-deductive (H-D) model of confirmation.

However, to begin confirming hypotheses about the observed record and build explanations about what happened in the past, archaeologists needed the linking universal laws. According to Binford this meant establishing "unambiguous cause-and-effect relationships between the causal dynamics and the derivative statics" (1983: p. 14). The operationalization of the New Archaeology would be a two-step process, then. For this reason, much archaeological attention turned to the processes responsible for transforming past behavior into the observed archaeological record. Two influential programs developed to secure the sociomaterial laws necessary for New Archaeology's fulfillment of the Hempelian ideal of scientific inquiry. Binford himself turned to ethnoarchaeology to study the archaeological record 'in the making' for his MRT (*see* Ethnoarchaeology). Michael Schiffer and his colleagues established a behavioral archaeology (BA) to study the relationships between human behavior and material culture in all times and places through ethnoarchaeology, experimental and modern material culture studies (Reid et al., 1975). There are important differences between these two approaches that bear upon New Archaeology's Hempelian philosophy. Most significant is the scale or applicability of generated laws. For instance, Binford, drawing upon a model of culture as a contained, self-functioning system, limits his generalizations derived from observation to the system-wide level. For Hempel inspired science, established laws were to be akin to those in physics and the other natural sciences, not restricted to spatiotemporal dimensions. Schiffer picks up on this inferred deficiency and attempts to begin at a nonculturally specific level of processes in order to generalize universally and cross-culturally

(Tschauner, 1996). Nonetheless, it was less the specific differences between these two influential currents of research and more the general assumption of uniformitarianism that united them which presaged the stringent criticisms of the New Archeology.

Post-Positivist Philosophy

Uniformitarianism, or the assumption that the principles observed in the present operated identically in the past, is central to both MRT and BA. It is difficult to imagine pursuing archaeology without such a belief. For philosophers of science, uniformitarianism represents the intractable problem of theory-ladenness. It is a more general example of where specific background assumptions influence the course of research. For Hempel, the division of theory from observation was crucial in his H-D model of independent testing. Yet, by the time New Archaeology was producing manuals on how to conduct Hempelian science (e.g., Watson et al., 1971), philosophy of science had largely conceded theory-ladenness. In large part this was due to internal commentators like Thomas Kuhn (1962) who convincingly demonstrated the role of 'extra-scientific' or social, political, and ideological factors that propel scientific progress. For archaeology, the substantive criticism of theory-ladenness and the possibility of the New Archaeology program as modeled upon Hempel's ideals quickly digressed into disciplinary quarrels. Philosophers of science chastised the new archaeologists for not only misunderstanding the details of Hempel's positivistic platform, but for being behind the times in not engaging the recent literature on post-positivist philosophy (Levin, 1973; Morgan, 1974). Archaeologists were being accused of not only doing bad science, but bad scholarship too.

At the same time, there was growing concern within archaeology that, despite drawing upon Hempel's models, the pursuit of meaningful generalizations was proving disappointing. Generalizations about the past were either severely restricted to specific systems or contexts, or too general as to be derided as 'Mickey Mouse laws' (Flannery, 1973). For instance, "objects left on a sloping archeological site wash downhill" (Flannery, 1982: p. 270). The quest for Hempelian covering laws was fairing little better in other sciences. Unsurprisingly, many New Archaeologists became somewhat disillusioned.

A result of these developments was an understandable disaffection with philosophy of science. Kent Flannery (1982) poignantly channeled this frustration with philosophy in archaeology in his parody of the 'Golden Marshalltown.' Philosophically minded archaeologists had lost touch with the dirt-driven details of actually doing archaeology. Robert Dunnell (1982) suggested that concept borrowing from philosophy of science had done a disservice to the discipline and that what was called for was an introspective examination of metaphysical principles. Schiffer (1981) urged the continuation of philosophical analysis in archaeology, but he noted that philosophers needed to better understand the epistemic problems particular to archaeological practice. This stance toward philosophy echoed David Clarke's (1973) earlier call for archaeologists to develop a discipline-specific philosophy.

Several philosophers sympathetic to archaeological pragmatics offered post-Hempelian advice. Drawing upon statistics, Merrilee Salmon (1982) discussed statistical-relevance (S-R) accounts of explanation and Bayesian confirmation and inference. Given the observed data, these models generate a statistical probability for how likely a specific hypothesis or explanation is relative to competing hypotheses. They also account for the updating of belief in a particular explanation with the accumulation of new data. The partnership of archaeologist Jane Kelley and philosopher Marsha Hanen (1988) produced an account drawing, in part, from an altogether different source of philosophy with pragmatism, embracing inference to the best explanation. For them, a satisfactory explanation is one that has more 'cash value,' to use pragmatist wording. Relative to competing explanations, it is the one that empirically coheres with more of the data and so accounts for, or explains, more. At the same time, an adequate explanation also theoretically satisfies or fits established principles. Guy Gibbon (1989), an archaeologist trained in philosophy of science, presented arguments from scientific realism that, contrary to positivist traditions, admitted 'unobservables' into the explanatory process. This is an important concession for archaeology, given the previous discussion of MRT and the admission that the causal processes responsible for the archaeological record are no longer directly observable. Similar to Kelley and Hanen, his scientific realism advocates a general version of inference to the best explanation. Finally, Peter Kosso (1992) unpacked inference to observation and draws upon models of multicomponent analysis used in the natural sciences.

Epistemic Settlements

Alison Wylie (2002), in a work that collects and develops her many essays bridging philosophy of science and archaeology, identifies the 'interpretive dilemma' that the discipline recurrently faces, demonstrating how theory-ladenness represents the most recent formulation of the intractable issue of relativism versus objectivity. Drawing upon scientific realism and feminist standpoint theories, notably Sandra Harding's 'strong objectivity' proposal, Wylie makes a compelling argument for mitigating the subjective bias of the observer (theory-ladenness) through, in part, turning the argument on its head. She argues that there are multiple checks, or 'tackings,' that occur both within and across the source-side (context of interpreter) and subject-side (relevant data) in the process of archaeological interpretation. Rather than attempt to remove subjective bias involved with background knowledge, assumptions, and proposed models, an ideal that post-positivist philosophy discredited, Wylie suggests bringing more interpreters and source-side models and assumptions to bear upon the data. Put simply, multiple sources of bias serve to mutually constrain one another in the interpretive process. For the subject-side of the equation, Wylie similarly explores how different sources and types of data interact to place limits on potential interpretations. Taken as a whole, these empirical and subjective constraints enter interpretation at several points, making it difficult for a coherent account to emerge. Wylie deploys the Peircean metaphor of the cable to indicate the strength of the inferences that result from weaving together these various components or strands of the interpretive process. Rather than a deductive procedure, Wylie's 'ampliative inference' nevertheless results in what she terms a 'mitigated objectivism.'

Wylie's epistemic settlement, much of which was worked out in earlier essays, appeared during this period of circumspect rapprochement with philosophy of science. Other epistemic settlements, in the wake of the New Archaeology, appeared over the same time. Notably Binford (1989), while accepting that observations are paradigm dependent (theory-laden), nonetheless advanced his more moderate 'relative objectivity.' By distinguishing between 'first order observation' and 'pattern recognition work,' Binford argued that archaeological data have a chance in the latter step to talk back, or challenge our initial observations. Bias enters into 'first order observation,' where human choice influences which attributes or qualities of the archaeological record are deemed relevant. However, the next stage of 'pattern recognition work' removes bias from the gathered data because it involves nonhuman, and so objective, measurements by technology. For example, while the archaeologist must identify and sample features or artifacts for radiocarbon analysis, a process that involves a host of decisions, the instruments and technology producing a range of dates for the samples do not involve a human 'subject.' They therefore produce objective data.

Worrying about a discipline strung along the spectrum from idealism to realism to positivism, Bruce Trigger (1998) drew upon Darwinian common sense to suggest that knowledge claims, in the present or past, work to aid our existence in the real world. The general idea is that for knowledge claims to be true they must correspond to reality. No matter how probable they initially appear, if such explanations do not match reality then they will hinder our adaptation to our complex environment. Consequently, false claims will be deselected over time. The hope was that such an evolutionary approach to epistemology, one that resonates with pragmatist accounts of truth confirmation, might offer a unifying, common-sense 'moderate relativism.'

Initially cast as hyper-relativist, Ian Hodder, over the course of the 1990s, drew upon hermeneutics, or the philosophy and method of interpretation of texts, to propose a 'guarded objectivity' as a solution to the evaluation of archaeological claims. With other so-called post-processualists, such as Michael Shanks or Christopher Tilley, Hodder argued for a strong contextualism of the archaeologist. While these archaeologists drew upon an alternate philosophical literary network, this might be understood as an expanded form of theory-ladenness. More strongly than its formulation in the philosophy of science, Hodder and his colleagues argued that the contemporary context of the archaeologist must be considered. It is a contextualism that draws more attention to the wider social, economic, and political factors brought to bear in archaeological activities. Hodder's (1999) framework for how these influences take part in archaeological research was described as the hermeneutic spiral of interpretation (**Figure 1**).

Rather than a vicious circle of interpretation, one leading to relativism, Hodder presents a reflexive analysis of how archaeologists make claims about the past and argues that the process is never ending (or only arbitrarily suspended). No definitive hypothesis testing or protocol is given for determining when a question has been decisively answered. Instead, questions lead to partial answers and, more importantly, the answers provided lead to further questions. These furthering on questions then prefigure, as incorporated into part of the archaeologist's own context, additional queries of the past. There are multiple, ongoing opportunities for the data to resist or disrupt the process, which would generate new questions. The result is a dialectic or, to use Gadamer's (1989[1960]) hermeneutic phrase, a 'fusing of horizons,' between archaeologist and past materials.

While there are sympathies in this process to Wylie's idea of multiple points of contact between the empirics and the archaeologist's background assumptions, Hodder's epistemic settlement differs in granting the archaeological material more agency in the process. It marks an increasing concern with ontology, or questions of what entities exist and how they relate, as opposed to epistemological concerns with how we

Figure 1 Visual rendering of Hodder's hermeneutic spiral of interpretation After Hodder, I., 1999. The Archaeological Process. Blackwell, Oxford.

know about such entities. While twinned to epistemology to form the pillars of Western philosophy, ontology had been little regarded by analytic philosophy, of which philosophy of science is a part. Furthermore, ontology and broader issues of metaphysics were explicitly regarded by the Vienna School, the progenitors of positivism, as nonsense and superfluous to the purpose of creating an observational language to facilitate making knowledge claims in science.

The Disunity of Science and Science Studies

Put within disciplinary context, these epistemic settlements can be appreciated as attempts for unification at a time when archaeology was seen to be splintering into a "thousand archaeologies" (Schiffer, 1988: p. 479). Some view the plurality of approaches as beneficial, drawing upon metaphors of democratic inclusion and racial diversity (e.g., Hodder, 2003). Others believe it to be worrisome and attempt to accentuate shared operational and reasoning principles among archaeologists despite apparent theoretical divergences (e.g., VanPool and VanPool, 1999). For example, despite the polarization, processual and post-processual practice was argued earlier on to be very similar. Tschauner (1996) suggested that post-processualists such as Hodder rely upon MRT and principles of BA to make arguments about the past in a manner similar to processualists. It has also been pointed out that regional techniques aside, methodologically both camps excavate in a comparable manner (Chadwick, 2003).

While regional specialties and methodologies create differences in practice, the perception of splintering is due in large part to groups of archaeologists orienting their craft according to versions of the epistemic settlements presented above. While these settlements are general heuristics of how archaeological reasoning proceeds, they nevertheless are informed by more specific and divergent background assumptions (such as how culture is modeled), operational procedures (is data acquisition strictly problem-oriented), and evaluative work flow (fitting in coherentism or testing under falsificationism). A result is that some archaeologists practice hypothesis testing or statistical relevance, others operate according to interpretive hermeneutics, and many more mix the various procedures in their overall practice.

Whether detrimental or beneficial for the discipline, the disunity of archaeology into semi-autonomous working camps is related to the discipline's former reliance upon the philosophy of science as well as the larger trend within philosophy of science toward dispersion. Former debates about how to properly pursue explanation of the past were more focal for the discipline, particularly with respect to the New Archaeology. They also drew, importantly, upon a small range of philosophies in their arguments (or in the case of the New Archaeology, two or three prominent philosophers). Discussion could anchor itself to common philosophical ground, as it were. Indeed, the unification of science was the explicit function of positivism according to the Vienna School founders. But whereas philosophers of science or philosophically minded archaeologists formerly could aid in arbitrating debates, there is now a philosophical vacuum left by the dispersion of philosophy of science into science studies.

Like Clarke (1973) or Schiffer (1981), within archaeology, the need to attend to the specific problems, practices, and history and social setting of a discipline was increasingly voiced by philosophers of science themselves. The problems of fit between philosophical models for inquiry and disciplinary practitioners' ability to put them to work were not restricted to archaeology. Other disciplines were experiencing a troubled engagement. Kuhn's (1962) analysis of how science progresses meant, among other things, that scientific practice was not served by idealized heuristics. It was far messier and contingent. Philosophers of science would need to work in the trenches (sometimes literally) to appreciate these contingencies and incorporate them into their models if they were to be of help. This recognition created a sort of crisis of relevance for philosophy of science (Stoll, 2000). Clearly, generating a single, comprehensive, and unified theory for how science works was no longer the goal of philosophy of science. Rather, it was necessary to acknowledge the specific workings of particular scientific disciplines in order to create accurate descriptions and models. In practical terms this meant that there were many sciences. In the face of what was called the disunity of science (Dupre, 1993; Galison and Stump, 1996), philosophers interested in science began to embed themselves in specific disciplines. Historians and philosophers of science, sociologists, and anthropologists, among others, increasingly found themselves under the umbrella of the emerging field of science studies. As Wylie (in Rathje et al., 2012) relates, the changes endemic to philosophy of science meant that if one was interested in pursuing a career, one had to be an 'amphibious philosopher': immersing oneself in a scientific discipline and obtaining practical training and credentials in the relevant fields of study. With philosophers of science attending more to the pragmatic details of particular disciplines, fewer general, trans-disciplinary programmatic statements have been offered. While some archaeologists still hold to concepts and heuristics of philosophy of science of the pre-Kuhnian period, these are largely implicit and infrequently discussed in open forums. Philosophy of science has largely gone underground in archaeology. Other varieties of philosophy have come to the fore of archaeological conversations.

Philosophical Pluralism in Archaeology

Due to the prominence of analytical philosophy in Anglo-American philosophy departments beginning in the early twentieth century, continental and pragmatist traditions within philosophy received little attention from archaeologists. There had been isolated exceptions, such as Raymond Thompson's (1956) use of the American pragmatist John Dewey. Yet with the growth of science studies and the decline in influence of analytic philosophy as handmaiden to science, many more archaeologists began to import ideas from continental sources. Interpretive or post-processual archaeologists drew upon a range of philosophers in their arguments against the positivist leanings of the New Archaeology. As noted above, Hodder cited hermeneutic authors, such as Collingwood, Dilthey, and Heidegger, and later Gadamer and Riceour, in developing his interpretive platform. Other post-processualists, such as Shanks and Tilley (1992), looked to social and political philosophers like Althusser, Bachelard, Derrida, and Foucault. Much less

consolidated around epistemic questions of scientific explanation, continental sources tend to be more interested in subjectivity and the role of the individual in society (as are some pragmatist thinkers). A broad range of social theorists were likewise enlisted to build arguments against some of the fundamental tenets that New Archaeologists had advanced. Among other differences, interpretive archaeologists construed culture as a dynamic between individual agency and societal structures rather than framed as the extrasomatic means of adaptation to the environment. The corollary meant that past cultures were not framed in ecomaterialist (or ecodeterminist) models, and so were less amenable to causal analysis. Hempelian models for scientific inquiry were viewed not only as overly idealistic, as post-positivist philosophers had argued with archaeologists, but also as inapplicable to archaeology's domain of study.

Such interpretive accounts, like Hodder's hermeneutic spiral, greatly contrasted with previous forms of evidential reasoning discussed in archaeology, whether analogical reasoning, simple inference and inference to the best explanation, falsificationism, and verificationism. Given the already circumspect relationship of archaeologists to philosophy of science, the new flurry of less familiar and seemingly eclectic philosophical sources in archaeological research cumulatively effected a largely negative reaction to the post-processualists. Perhaps perceived as adding insult to injury, there had been a fairly quick succession of (at times acrimonious) theoretical debates involving philosophy in archaeology.

The array of philosophical sources introduced to archaeology continues unabated. As one example, the compendium, *Philosophy and Archaeological Practice* (Holtorf and Karlsson, 2000), added philosophers as disparate as Feyerabend, Irigaray, Levinas, Merleau-Ponty, and Wittgenstein. The use of these philosophical sources varies greatly. Many are employed in a manner similar to what philosophers of science would regard as source-side work, that is, the development of new models for investigation in a manner similar to the role that ethnographic analogy served MRT. At other times, certain philosophies are used to build up a more thorough-going archaeological program, extending from problem formulation through to modes of investigation and sometimes explanatory justification. Tilley's (1994) use of Merleau-Ponty and Julian Thomas' (1996) work with Heidegger to develop phenomenological approaches to landscapes are notable examples. Here the archaeologist himself or herself is used as an analog for past individuals' perception of archaeological features. Another example is Robert Preucel's (2010) refinement of Hodder's initial work on hermeneutics and the active role of archaeological materials for the interpretive process with his use of American pragmatist C.S. Peirce's semiotics. Here Peirce's tripartite scheme of icon, index, and symbol is used to demonstrate how cultures and social groups variably ascribed meaning to materials and how such materials had a part within social contexts to determine their own significance.

In addition to these continental- and pragmatist-inspired approaches, there continues to be sporadic engagement with post-positivist philosophy. As a sampling, William Krieger (2006) argues for the mutual benefit that would result from archaeology reembracing the scientific realism of Bunge and Harré. Sandra Wallace (2011) presents Bhaskar's critical realism and suggests that its concern with open systems, in contrast to scientific ideals of closed, laboratory-like systems, could better model past societies. She also contends that critical realism's concern with 'depth ontology' could aid archaeology in avoiding unhelpful dichotomies, such as that between the social and material, or between explanatory tendencies of reduction and conflation. This is because critical realism is a relational approach to ontology that emphasizes shifting internal relations among different levels or strata that make up reality, such as the social, biological, or material. The hope is to avoid conventional conceptions of reality that are argued to be either too atomistic, with reality composed of individual and distinct bits, or overly holistic, with reality being an undifferentiated soup. In addition, and similarly to Gibbon's 'unobservables' in his scientific realism, absence is theorized to be real and have effects in Wallace's relational account.

Current Orientations

Despite this diversity of uses for, and types of, philosophy in recent archaeology, several emerging research orientations have refocused upon science studies as the contemporary inheritor of philosophy of science. Most of these work with ideas developed by ethnographers of science in observing the practicalities of 'science in action' (e.g., Latour, 1986). Sometimes identifying themselves as science and technology studies (STS), these observers have influentially drawn attention to the active role of things (objects, instruments, inscriptions) as they operate as networks with humans to accomplish tasks (Webmoor, 2013). Many of these STS scholars have explicitly rejected epistemology as being unhelpful due to its deep-seated assumption of a subject–object split (often attributed to René Descartes). One resulting mantra has been to avoid making assumptions beforehand regarding what or who the 'actants' are in any given investigation (hence modifying the human-centric term in favor of actant).

Andrew Jones (2002) draws upon science studies in his account of archaeological practice. Demonstrating that archaeological materials have agency in partially determining their interpretation, he offers an integrationist approach that obviates concerns over subjectivity and objectivity and might unite science-based and interpretive archaeologists. Combining insights from philosophy of mind, cognitive science, and STS, Carl Knappet and Lambros Malafouris (2008) develop Colin Renfrew's cognitive archaeology in nonanthropocentric directions. Drawing upon a range of archaeological examples, from experimental studies with pottery making to reflexive analyses of archaeological recording, Knappet and Malafouris focus attention on the manner in which action in the past is never the exclusive domain of social or material factors.

Those advocating relational ontology likewise bring attention to nonanthropocentric ideas of identity and agency in the past, such as the mutual constitution and dependence of humans, nonhumans, and other life-fellows. Christopher Watts (2013) brings together an assortment of archaeologists who draw upon STS authors, indigenous metaphysics, and continental philosophers, such as Deleuze, Guattari and Manuel De Landa, to develop a concept of existence as an

emergent, fluid assemblage of connected components rather than a fixed and stable given. The emphasis upon ontology for most of these scholars alters the role and practice of the archaeologist. It shifts from a traditional concern with accurately representing the reality of the archaeological record, to presenting alternate possible realities of the past.

Olsen et al. (2012) draw together this growing interest in ontology and material agency by articulating a dissatisfaction with the increased prevalence of social constructivism and social theory more generally in a discipline that is, as they remind archaeologists, surely 'the discipline of things.' Working with STS, but also engaging with a group of trans-Atlantic philosophers who identify as speculative realists (e.g., Harman, 2010), the authors present a series of arguments for how taking seriously the active (but nondeterministic) role of materials involved in the practice of archaeology might contribute to disciplinary self-confidence vis-à-vis philosophy or other social sciences. To do this they offer the principle of symmetry as an attitude regarding reality that avoids a priori theorizations about the nature of things, as in relational, atomistic, or holistic accounts. Instead, they advocate the unique expertise of archaeologists to empirically document settings whereby any conception of the realities involved is an outcome, not a starting point. For example, careful recording of an artifact and its context enables postexcavation analysis where it may emerge that objects and their qualities are the locus of explanation, or, alternatively, that the entire assemblage with its relations needs emphasizing, or that a dialectical explanation moving between singular objects and the larger contexts fits best. The point is that the principle of symmetry applied along the entire workflow keeps archaeologists agnostic until the empirics overwhelmingly compel. This ontological outlook avoids privileging relations among things, the relations themselves, or the inherent qualities of things themselves.

In all there has been a discernible shift in archaeology toward an engagement with science studies and a wider suite of philosophies. This has accompanied a greater complacency toward issues explicitly concerned with epistemology and a growing interest in ontology and the role of the material in human life past and present. Given the wider conversation taking place across the humanities and social sciences around the importance of material things, archaeology and philosophy's current engagement stands to make a vital contribution to these wider matters of concern. Despite the changes over their long history of interaction, the partnership of philosophy and archaeology stands to continue in new and interesting directions.

Abstract

From the inception of academic archaeology, the position of theory in the discipline has been marked by influences from other fields of research, both in terms of the concepts applied and the general outlook on the proper modes of investigation. The relationship between theory and method has remained an open issue for archaeologists, not resolved by two massive changes usually marked by the processual shift of the 1960s and the postprocessual critique from the 1980s. The recent developments aim to address this tension, but the academic community remains fragmented and archaeological theory diverges in several disparate directions.

The aim of the discipline of archaeology is to make inferences about the past based upon the material evidence of human activities. Consequently, the role of theory in archaeology is to provide the general framework of propositions and principles according to which the material record may be investigated in order to reach scholarly verified reconstructions of the past. This set of premises has changed throughout the history of the discipline and it has become customary, over the last couple of decades, to regard these developments in archaeological theory according to a pattern of stages, starting with the antiquarian beginnings and then proceeding to the culture-historical, processual, and eventually postprocessual strands of research (cf e.g., Hodder, 1991a; Jones, 2002; Johnson, 1999; Olsen, 2002; Renfrew and Bahn, 2005). This pattern, though a useful heuristic device in its own right, opens up several questions that need to be addressed. Firstly, as is always the case with generalized statements, it leaves aside a plethora of divergent paths and local particularities of archaeological theory and practice around the globe (Babić, 2014; Biehl et al., 2002; Gramsch and Sommer, 2011). Furthermore, this neat sequence may imply that as the discipline matured, so too did its theoretical apparatus, constantly moving toward more sophisticated ways of understanding the past (cf Hodder and Preucel, 1996: 4). And yet, "every once in a while archaeological theory gets a bashing" (Lucas, 2012: 1). This is a somewhat peculiar position for theoretical considerations inside an academic discipline since theory is usually considered to be the very foundation of any particular field of research. It has been suggested that these 'occasional bashings' are the result of the potential schism between archaeological theory and method, apparent at least from the 1960s (Lucas, 2012; cf also Jones, 2002). This enduring tension may be the result of the underlying assumptions and traditions that structure the work of archaeologists and the ways they accept, adapt, and apply theoretical concepts (Johnson, 2006).

Theory and Method

Indeed, from the inception of the discipline to the present day, archaeologists have been influenced by various ideas shaped in other fields of research, but have not always been inclined to overtly acknowledge these sources of inspiration. These idea transfers have been induced by the perceived similarities of the object and aims of research, as well as by the generally accepted premises of scientific work, not only in the field of humanities and social sciences, but also in the domain of hard science. Some of the basic principles of archaeological research have therefore been shaped by the generally prevailing ideas on proper scientific procedures and methods for procuring knowledge, regardless of the type of evidence and goals of a particular field of inquiry. Commenting on this, Julian Thomas (2004: 55) emphasizes archaeology's adherence to a conception of knowledge that privileges method over theory, ascribing this inclination to the discipline's eminently modernist character. He traces the roots of the primacy of method over theory back to early modern philosophy and René Descartes' *Discourse on Method*, which defined a program of rational understanding of the world through rigorous adherence to a defined procedure. Descartes' aim was to overcome the prejudices and uncertainties of the time by means of radical doubt and dismissal of any knowledge that could not be substantiated by hard evidence. In his program, Descartes was responding to his own age, when the European world was changing; fighting to come to terms with these changes, most of them caused by the upheavals of the Reformation; and rapidly expanding scientific discoveries and encounters with non-Western societies through colonizing and mercantile expansion (cf also Gosden, 1999, 2004). Therefore, Descartes asserted that the gathering of knowledge from the world had to be carefully regulated, guided by the use of reason, ultimately leading to universal truth. Methodology thus became a means to order and regulate the process of knowing the world and its absolute and objective truths that was not dependent upon theoretical assumptions. The influence of Descartes was profound and, through the Enlightenment philosophy of the eighteenth century, his ideas pervaded all fields of inquiry, implying that there is one single legitimate linear procedure for the acquisition of knowledge (Thomas, 2004: 55f.). Method prevailed and theory drifted far away from its original meaning.

The word *theory*, along with its many forms in modern languages, is derived from the Ancient Greek *theoria*. The term has a number of meanings, some of them preserved in its modern usage: "a set of statements or principles devised to explain a group of facts or phenomena; the branch of a science or art consisting of its explanatory statements, accepted

principles, and methods of analysis, *as opposed to practice*" (American Heritage Dictionary, 2009, emphasis added). And yet, in its original usage, the Greek *theoria* encompassed a particular practice, that of traveling to foreign lands and observing the customs of other peoples, in order to achieve wisdom (*sophia*) necessary to improve the home state (Euben, 2006: 21). The travelers were appointed from among the most experienced and esteemed citizens. Their voyage was not to exceed a 10-year period and, upon their return to the homeland, the knowledge they acquired was examined, as well as the possible consequences of the experience of travel upon the *theoroi*. If their observations proved to have enhanced their wisdom, they were celebrated and honored in life and death. On the other hand, if a traveler – *theoros* – returned from his voyage 'corrupt,' he was to be isolated from his country-mates and even punished (Plato, *Laws XII*, 951 a–c; see also: Euben, 2006: 21; Redfield, 2002: 25; Leontis, 2001).

So, knowing about aliens was not a light affair among the Ancient Greeks – it was carefully planned, evaluated, and sanctioned. Indeed, it never is perceiving similarities among members and differences with outsiders is the basic principle of forming a group and laying out its ground rules, a process inevitably linked to some form of authority (cf Levinas, 1989; Todorov, 1989). With the advent of the age of modernity, the task of discerning and legitimizing the limits of human groups of all kinds was assigned to academic institutions and scholars in the fields of social sciences and humanities (Thomas, 2004). In this new distribution of authorities, archaeology is positioned as the field of knowledge in charge of the deep past of humankind, reaching back to periods of illiteracy and therefore inaccessible to historians. For lack of written evidence, the explanations of the customs of our ancestors were to be sought in another direction, that of the peoples still living in far off lands, unaffected by the progress of the European civilization. The notes of travelers to Africa or the Americas, describing the strange ways of life of the Others who lived there, shook the world at the times of Descartes and thus became a source for the understanding of our own remote past (Johnson, 1999: 133, 134; Wylie, 2002: 137).

General Law of Development

This initial alliance between distance places and European pasts foreshadowed several points crucial for the future development of theory in archaeology. First of all, archaeology's subject matter has been defined as a culture remote in time, and yet comparable to the ones remote in space. At the same time, this comparison between the Other and the past implied that there is a general framework according to which these comparisons are made, encompassing all possible forms of human organization, ordered in a logical sequence, leading from simpler, less developed, to more complex forms. This general pattern of development was introduced to archaeological thinking from other fields of research: it has a long history in social sciences and humanities, starting again with the Enlightenment of the middle of the eighteenth century and is still present in its refined, but essentially unchanged forms, under the title of 'social evolution' (Pluciennik, 2005). This concept implies that human societies are expected to move along a more or less predictable trajectory of development, with individual groups being 'caught' by observation in one particular 'stage' at a particular time. The remote past and the remote lands have thus been brought into a permanent metaphorical association: the state in which the European researchers have encountered their non-European informants during the ethnographic observations has been removed from modernity, pushed into the past, wherefrom 'we' have long progressed, and this progress is testified by the archaeological record of the European prehistory (Fabian, 1983; Johnson, 1999: 132–137; Gosden, 1999, 2004, 2007).

This starting premise, like most of the other theoretical assumptions of the late nineteenth and early twentieth century archaeology, has remained largely implicit, leading subsequent researchers to emphasize the essentially descriptive character of the culture-historical approach – the set of rules and methods typical of archaeological research in this period (Johnson, 1999: 15, *passim*; Olsen, 2002: 30–33). Nevertheless, the descriptions produced on the grounds of these implied but never clearly stated assumptions have pervaded archaeological interpretations of the past, underlying the cultures uniquely successful on the trajectory of development and emphasizing their value as role models for the present. In the process, the most desirable ancestors were singled out, such as the great civilizations of Greece and Rome (Babić, 2010). Archaeology, along with the other fields of research, was fulfilling its social purpose: the past was uncovered, described, compared to other accessible samples of human behavior, valorized, and offered to the public in the form that enabled the audience to make sense of its present condition. However, this practice left out huge tracts of the past that still needed meaningful links to the present, and arrowheads and sherds still floated over the spaces now inhabited by the modern nations without the proper names for the people who made and used them. Archaeologists were in dire need for the principle to organize these traces of the past into comprehensive units. The solution is best described in the words of one of the most influential figures in the history of the discipline, Vere Gordon Childe:

> We find certain types of remains – pots, implements, ornaments, burial rites, and house forms – constantly recurring together. Such a complex of associated traits we shall term a 'cultural group' or just a 'culture.' We assume that such a complex is the material expression of what today would be called a 'people.'
>
> Childe, 1929: v, vi, emphasis added

It may safely be argued that this statement discloses the fundamental theoretical principle underlying archaeological research over the long period from the beginning of the twentieth century into the present. The logic behind it is the premise that the objects made and used by humans are the direct expressions of cultural norms – rules according to which people behave (Johnson, 1999: 16, 17). These rules are then equated to the modern experience of belonging to a nation state, with its fixed boundaries and authorities unifying social, political, and economic behavior of subjects throughout a contiguous territory (Thomas, 2004: 96–118). Furthermore, the assemblages of material culture identified over certain territories are again sorted into a chronological sequence,

from technologically and therefore culturally less developed ones to the more advanced forms, all ultimately leading to the present (Jones, 1997; Lucy, 2005; Thomas, 2004: 111). The notorious case of Gustaf Kossinna offers a drastic illustration of the ultimate consequences of this line of inference: by the beginning of the twentieth century he established a direct relationship between material culture, the people producing it, and the language they spoke, enabling the researchers to equate sharply delineated archaeological cultures with the areas occupied by clearly recognizable peoples or tribes. This idea lays heavily upon the works of the late nineteenth-century German anthropologists, such as Friedrich Ratzel, Leo Frobenius, and Fritz Graebner, who established the idea of *Kulturkreise*, or homogeneous, organically integrated cultural complexes, as a part of their *Kulturhistorische Methode*, devised to ascertain historical sequences on the basis of the contemporary geographical distribution of culture complexes (Jones, 1998: 46; Lucy, 2005: 87; Olsen, 2002: 117–121). By projecting the areas of modern ethnic or national units onto the past, Kossinna established cultural and therefore ethnic continuity, opening up the path for the justification of the control over territories based on ancestral rights (Jones, 1997: 16–17; Lucy, 2005: 87; Thomas, 2004: 110–111).

The possibility to harness the archaeologically recovered past for the present political purposes has not remained unexplored, and from the days of Kossinna and his overt involvement with the official German claims over parts of Poland (Thomas, 2004: 110), to the much more recent turmoils in many parts of the world, archaeological interpretations of the past have been harnessed for present-day purposes, arguing that cultural groups of the past are in fact embryos of the modern nation states (cf Kohl and Fawcett, 1995). The danger of slipping into the realm of abuses was already apparent to Childe, and he rejected Kossinna's racist assumptions and stated especially in his later writings that an archaeological picture of culture was built up out of many fragments, registered at various times in different places (Lucy, 2005: 88; Olsen, 2002: 37). However, the basic premises according to which archaeological cultures have been discerned remained largely the same and, along with the procedures for organizing material, the theoretical premises of Ratzel and Frobenius upon which these procedures were designed percolated to archaeology too, bringing along current ideas about human groups in general. In this fashion, cultural groups were invested with the characteristics of the modern nation states and the archaeological record interpreted along the lines of the eminently modern experience of group identity, one based upon ethnic affiliations organized into large political entities. Once more archaeologists, Childe and Kossinna alike, partook in the prevailing intellectual climate of the age, received ideas from other fields of research, and adapted them for the purposes of their own quest for the past (cf Thomas, 2004: 94ff.; Olsen, 2002: 33–37). The abuses of archaeological inferences drawn in such a manner were apparent even to Childe, who amended his views and already in the mid-1930s started experimenting with other theoretical premises for archaeological thinking, devoting considerable attention to social and economic aspects of past societies, informed by Marxism (Olsen, 2002: 142–143; Patterson, 2003: 42–62). Nevertheless, the concept of cultural group proved to be extremely durable and has marked almost a century of archaeological research. It survived almost intact the first explicitly theoretical shift in archaeology, unfolding during the 1960s under the name of the 'New Archaeology,' and later renamed 'processual archaeology,' a perspective that expressly aimed at overcoming the fallacies of the culture-historical approach.

Explicitly Scientific Archaeology

The proponents of this new outlook ardently argued that the discipline needed a much more explicit theoretical foundation than the one previously practiced in the culture-historical framework. They purported that its descriptive character did not offer answers beyond classification of material culture of the past (Johnson, 1999: 12f.; Olsen, 2002: 43–56; Wylie, 2002: 23 f.). In order to overcome this petrified state of the discipline Lewis Binford, the main protagonist of the critique of the 'traditional approach,' claimed that archaeology is and indeed must be anthropology, both in terms of disciplinary goals and the wider frame of reference (Binford, 1962). This proposition was strengthened by the institutional divisions of North American universities, where archaeologists have been members of anthropology departments and are basically trained under the same banner. Binford himself was a student of Leslie White, the anthropologist whose tenets soon formed one of the building blocks of New Archaeology (Olsen, 2002: 44, 45, 48, 49). White's functionalist view of culture as an organism with mutually dependent parts or subsystems closely related to the natural environment heavily influenced the newly formulated ideas about the research of the past (Johnson, 1999: 64f.; Sabloff, 2005: 214). Binford and his associates argued that the technological, economic, social, political, and ideological aspects of past societies, inextricably intertwined with the environment they inhabited, can be approached through the material culture and other physical traits that past activities left behind.

This explicit agenda opened up the issue of the practical procedures enabling archaeologists to meet the goals of translating the material traces, now tangible, but static, into the dynamics of past processes or, in other words, to bridge the gap between the archaeological record and past behaviors. This new device came to be known as middle-range theory (Gibbon, 1989; Johnson, 1999: 49–63; Olsen, 2002: 50–51; Sabloff, 2005; Wylie, 2002: 17). The most productive way to link behaviors with their material consequences were found in ethnoarchaeology and experimental archaeology – controlled observations by archaeologists of living populations' activities and their material consequences under particular environmental and cultural situations. The data gathered in this way are then compared to archaeological record, following the premise that the behavior observed by researchers of modern populations may be analogous to ones in the past leaving the same material trace. Binford himself studied the North American Nunamiut population, with the goal of explaining the archaeological record of the prehistoric hunter-gatherers (Binford, 1983). The comparisons are then guided by the mode of explanation predominant in hard

sciences: problem-oriented hypothesis testing, following the hypothetico-deductive model of confirmation (Gibbon, 1989; Wylie, 2002: 2–4). However, this procedure was merely making explicit and methodologically rigorous what archaeologists have been doing from the late nineteenth century – comparing the Other in space to the Other in time.

The insistence on experiment and observation still apparent in the program of processual archaeology testifies to the commitment to a rigorously empirical form of inquiry. This approach echoes the foundations of modern science laid by Descartes and may be traced back to Carl Hempel, philosopher of science who strongly and consistently argued for logical positivism, rooted in the empiricist conviction that legitimate knowledge is properly grounded in testable observables (Gibbon, 1989: 10f.; Wylie, 2002: 2–4). This approach inevitably led to a strong emphasis on various scientific methods applied in archaeological research, such as petrography or palaeobotanics, and accelerated the development of disciplinary branches such as zooarchaeology. The texts produced by processual archaeologists did change substantially in their form and content, with all kinds of diagrams and quantified observations taking center stage. At the same time, equally quantified means came to be used to describe and explain the actions of humans in their environment, producing models of behavior. Site catchment analysis (Bailey, 2005) and blueprints of exchange systems (e.g., Renfrew, 1975) were followed by check-lists that would ensure the identification of certain forms of social organization in the archaeological record (e.g., Peebles and Kus, 1977). However, these forms were sought on a universal ladder of social evolution (e.g., Friedman and Rowlands, 1977).

A focus on universal social forms should not come as a surprise, since the principal aim of New Archaeology has been to formulate lawlike conclusions about the past and bring them in accordance to scientific knowledge in general. As a consequence, the discipline reestablished the concept present in its theoretical toolkit from the very beginning – that human culture progresses through universal and predictable stages of development. Admittedly, the iteration induced by processual archaeology differs from the previous situation in the discipline, since now the concept is clearly articulated and explicitly stated. Nevertheless, the burden of its inception still remains, and substantial efforts invested in its refinement over the last decades have not yet fully resolved the in-built threat of valorizing human groups according to their 'stage of development' (cf Pluciennik, 2005). Even more importantly, the adherence of New Archaeology to the concept of social evolution highlights the fact that at a time when archaeologists explicitly and programmatically turned to social anthropology for theoretical support in the project of making the discipline more explicitly scientific, anthropologists themselves were slowly but steadily abandoning the evolutionary and functionalist approaches proposed by Leslie White. Simultaneously, in other fields of the humanities and social sciences, philosophy as well as history, the positivistic ideal of scientific objectivity was severely challenged (Olsen, 2002: 55). Instead of bringing the discipline closer to other fields of research and endowing it with a sound theoretical foundation, it may be argued that the movements during the 1960s and 1970s were in fact leaving intact some of the crucial points present in archaeology from its inception as an academic discipline. This may be obvious in the fact that the mighty tide of change left aside the concept of cultural group without challenging it and even sporadically used it as a practical principle for organizing material before subjecting it to the scientific analysis.

Troubles with Science

The first critical reactions to the program of New Archaeology were articulated almost simultaneously to its publication. Particularly important, although perhaps too harsh, are the objections judging that the program offered was predominantly a methodological shift, rather than theoretical, leaving the conceptual core of the discipline almost intact (Wylie, 2002: 25–41). The modernist notions about the scientifically valid procedures in line with the writings of Descartes present though not always explicit in the history of the discipline, in the case of the processual program are indeed deliberately emphasized. On the other hand, even the authors acknowledging the theoretical dimension of the processual program point to the limitations of the logical positivistic agenda in general and in particular to its applicability to archeological research (Gibbon, 1989; Wylie, 2002: 17–19). The critique may start with the position that science itself is a social process, in which theory is dependent on observations mediated by methodological rules. These rules, in turn, direct what kind of observations will be considered valid, generating a circular line of inference, where methods based on assumptions about the nature of the object of study produce observations that must confirm the starting assumptions. Here, the general objection to logical positivistic program, that all sciences need not share the same methodological and substantive base, is extended to emphasize that humans possess consciousness, volition, and reflectivity, setting them apart from natural phenomena. The mechanistic conception of human beings and their actions, imminent in positivistic research agenda, are therefore seen as particularly damaging to disciplines such as archaeology (Gibbon, 1989: 35–60). The valorization of the decades' long implementation of the principles of processual archaeology based upon logical positivism seems to prove these claims, since very few formal lawlike statements or theories were ever produced, but a series of hypotheses testing in need of further systematic restatements (Gibbon, 1989: 94).

In retrospect, many claim that "an empiricist account of science must fail to provide laws of social life equivalent in scope, certainty and predictive capacity to those offered by natural science," so "New Archaeologists launched a program that was impossible to carry to completion" (Gibbon, 1989: 117). There can be little doubt, however, that the processual claims for a more methodologically rigorous and problem-oriented archaeology have induced significant changes in the discipline and many archaeologists around the globe still test its interpretive potential. On the other hand, the universal consensus about the theoretical grounds upon which archaeologists should seek knowledge about the cultures different from our own and remote in past – about the Other

in time – has not been reached and whether Lewis Binford put in motion a revolutionary paradigm shift in theoretical terms remains an open question (cf Olsen, 2002: 54–56, *passim*).

The proponents of the next reconsideration of the aims and means of the discipline, emerging by the beginning of 1980s, picked up many of the already mentioned weak points of the processual stratagem. The term to denote these diverging critiques, postprocessual archaeology, announces the dissatisfaction with the processual achievements, but at the same time seeks allegiance with all forms of thinking loosely encompassed with the label postmodern. Following the cue from other humanities, although with a delay of several decades, archaeologists started questioning the suitability of the positivistic imperative for their own research purposes (cf Hodder, 1986; Shanks and Tilley, 1987). Some archaeologists started arguing that the deep embeddedness of research into its contemporary social, cultural, and political circumstances cannot be overcome by pursuing the rigorously scientific procedures, themselves also subject to various pressures and conditionalities of the context of inquiry (Bourdieu, 1988). Rather than working hard at closing out these 'disturbances,' the attempts have been made to contextualize the discipline in its modern setting (Hall, 2000; Thomas, 2004). The issue of authority, apparent already in the Ancient Greek practice of theory, came to the forefront of discussions on the social role of archaeologists (Shanks and Tilley, 1987; Tilley, 1989). The path has been opened to reconsider the conceptual burden of the discipline built into its modern foundations (Thomas, 2004), enabling the researchers to realize that our reconstructions of the past have been heavily influenced by our own preconceptions of ourselves and of the modern Other. These preconceptions range from the ones concerning not only the cultures different from ours (Gosden, 2004, 2007) but also the differences among the individuals in our own society, such as gender (Gero and Conkey, 1991; Gilchrist, 1999; Sørensen, 1999), age, status, and religious or ethnic affiliations (Díaz Andreu et al., 2005; contributions to Insoll, 2007). The change of focus brought into the archaeological research the ideas of possible ways of articulating individual identity other than the ones constructed during the modern age (Fowler, 2004; Thomas, 2004: 119f.). Even the experiences of time and space, previously thought of as universal to all human beings and therefore susceptible to objective observation and plotting onto archaeological charts, have become the subject to investigation (Johnson, 2007; Lucas, 2005).

This turn requires a reconsideration of the material we work with – the archaeological record. While culture-historical and processual approaches equally consider the record to be comparable to a contemporary material context, yet remote in time, the postprocessually inclined authors tend to emphasize its fundamentally historical nature (Lucas, 2012: 8; Patrik, 1985). This basic distinction of the ways in which archaeologists approach their subject matter may be translated into the two models of archaeological record: the physical and the textual, each with a corresponding theoretical background and methodological implications (see also Jones, 2002: 10, 11, 17). As opposed to the concept of (past) material culture as a static physical representation of human actions, susceptible to objective observation, classification, and quantification in a manner similar to natural phenomena, the textual model of archaeological record presupposes that material culture is meaningfully constituted, active, and used by people to convey meanings. The rules according to which these meanings and messages are structured and understood are culturally specific, and the task of archaeologists is therefore to 'read' (Hodder, 1986) or interpret them (Thomas, 2000), rather than explain them in terms similar to hard science.

In order to meet this proposition of Ian Hodder and others, archaeologists had to depart from the previous inspirations in the anthropological literature, such as social evolutionism and functionalism, and seek allegiance with the theoretical reconsiderations transcending disciplinary boundaries between philosophy, sociology, and literary theory among others. The hermeneutics of Paul Ricoeur and the poststructuralism of Michel Foucault brought into archaeological thinking the issues of subjectivity, discourse, and intertextuality (Bapty and Yates, 1990; Tilley, 1990). Furthermore, the concepts developed by Pierre Bourdieu (1977) and Anthony Giddens (1979) were picked up by archaeologists (e.g., Dobres and Robb, 2000; Johnson, 1989; Thomas, 2000), introducing a theory of practice into the discipline. Humans, both present and past, are seen as endowed with *agency*, or the capacity to act individually and to make choices, that may be opposed to structural constraints imposed by *habitus* – a set of values and dispositions acquired under the particular cultural circumstances. Human groups therefore construct collective knowledge with shared meanings ascribed to the world and have in-built potential to change. The change, however, need not be easily predictable according to preconceived rules. Rather than search for universal regularities in social processes, the discipline shows interest for particular experiences of individuals.

Archaeology and Its Contemporary Context

In the course of these reconsiderations of the discipline, its own practices have become the object of research in their own right. It has become apparent that underlying theoretical assumptions influence the methodological aspects of archaeological work down to the very procedures of data collection in the field (Lucas, 2001). At the same time, the valuable legacy of the processual strain of research – the application of hard science analyses – is not neglected, but this remains an uneasy cohabitation, due to the differing logic behind the positivist and constructivist approaches (Jones, 2002). In spite of the efforts made in this direction, the frequent objection that the postprocessual approach represents 'theory without method' (Lucas, 2012: 2) still looms large. It may be argued that the departure from the initial theoretical foundations of the discipline brought about in the 1980s induced changes more profound than the processual shift, but stripped off its methodological certainty. It is therefore not surprising that a significant number of archaeologists around the world still remain largely uninterested in the theoretical debate and adhere to the methodological practice produced as a result of hybridization of culture-historical and processual approaches. Furthermore, various locally specific conditions of the institutionalization of archaeology have brought an array of particular responses to the general pattern of 'the three stages,' similar to the one proposed for the European prehistory by early researchers such as Christian Thomsen (Babić, 2014;

Biehl et al., 2002; Gramsch and Sommer, 2011; Sklenář, 1983), sometimes resulting in diametrically opposing outcomes from the same theoretical starting point. The archaeological involvement with Marxism may serve as a highly illustrative example (cf McGuire, 1992; Patterson, 2003). Matthew Johnson therefore rightfully concludes that "the claims for a distinctive way of thinking about the world in theoretical terms specific to archaeology, to which most or even the largest group of archaeologists would willingly or knowingly subscribe, are over-stated" (Johnson, 2006: 117).

Abstract

Archaeometry is the application of the various sciences in archaeology to determine age, composition, structure, origin, production technique, resource exploitation, and environment. This field of research includes radiocarbon, luminescence, and other numerical dating methods, geochemical and mineralogical analyses, metallurgical studies, and stable isotope chemistry. The scope of archaeometry is expanding and diversifying as new physical and chemical analytical techniques are employed to provide archaeologists with answers to questions about natural and human artifacts, site characteristics, organic remains, and past environments.

Archaeometry

'Archaeometry' is a specialized discipline within archaeology in which various scientific methods of chemical and physical analysis are applied to archaeologically derived materials. Archaeometry therefore centers on research whose aim is to explain and test archaeological questions about ancient things or phenomena related to human cultural activities. The research measures or quantifies parameters using analytical techniques borrowed from earth science, chemical, biological, and other scientific disciplines. The field of archaeometry includes, for example, determining the ages of sites and artifacts, sourcing objects to the original localities of raw materials, identifying the components and processes involved in converting earth materials into metals and ceramics, and determining patterns of dietary exploitation. Many analytical techniques have been applied in these investigations and some common ones are briefly described below to illustrate the diversity of archaeometric techniques.

Age Determinations

Probably the first example of the use of archaeometrical methods was the realization that the annual growth rings of trees could be used to determine the age of construction of prehistoric pit houses in the southwest of the USA using cores taken from wooden beams (Douglass, 1936). The tree rings were also shown to indicate variations in climate within the time span of the life of the tree (Judd, 1954). This method of tree-ring dating, or dendrochronology, is still widely used to date habitation sites in the Americas and in Europe.

The dating of carbon-bearing substances associated with archaeological deposits has revolutionized the determination of absolute ages in archaeology. Radiocarbon dating (Libby et al., 1949) has been used to place time markers on important periods of human activities and climatic change, and to date the extinctions of animals, for example the woolly mammoth and sabre-toothed tiger (Ho et al., 1969). Refinements to the method and development of the accelerator mass spectrometer (AMS) have allowed for the dating of microgram quantities of carbon (Nelson et al., 1977). For example, a famous case involves the AMS radiocarbon dating of the Shroud of Turin (Damon et al., 1989). While many people believe the shroud was wrapped around Christ's body, fragments of its linen fibers were dated independently by three radiocarbon laboratories to the late thirteenth century.

Archaeologists have also been able to date individual seed grains, beeswax resins (Nelson et al., 1995), charcoal scrapings from Paleolithic cave paintings (Valladas et al., 1992), and buried Australian rock art (Watchman, 1993). Pigment painted on rock in South Africa was the first application of the AMS radiocarbon technique for dating rock art (Van der Merwe et al., 1987). Innovative methods have since been developed for extracting carbon from paintings. Oxidation of carbon compounds associated with pigments or rock surface mineral deposits using either an oxygen plasma (Russ et al., 1990), laser energy (Watchman et al., 1993), or permanganate chemistry (Gillespie, 1997) can be used to prepare samples prior to AMS radiocarbon dating. Rock art in Texas has been dated to between 4100 to 3200 years ago (Russ et al., 1990). Rock paintings in northern Australia have been dated using carbon in rock surface encrusted 'canvasses' and mineral coatings (Watchman, 1993) and in plant fibers used as paint binders (Watchman and Cole, 1993).

Analytical methods employing light (luminescence) are also being used to date sediments in occupation shelters and in pottery. The basis of the luminescence methods is that natural radiation provides energy to the electronic structure of some crystals, particularly quartz and feldspar minerals (Aitken, 1985). Grains that are heated (thermoluminescence, TL) or illuminated by green light (optical luminescence) emit small amounts of light that reflect the level of radiation and length of time since they were incorporated in a sediment or pot. In a controversial case the floor sediments containing stone artifacts at Jinmium in northern Australia were dated at 116 000 years old using TL and quartz grains (Fullagar et al., 1997). The age of those sediments were disputed by proponents of an optical stimulated luminescence method (OSL) who found that the maximum age of the deposits was only 10 000 years (Roberts et al., 1998). Arguments about the reliability of the age determinations for the sediments are concerned essentially with bulk-samples versus singlegrain analyses, incomplete bleaching by sunlight of the luminescence centers in quartz grains generated by *in situ* disintegration of

rock fragments compared with well-bleached sand grains. These controversial situations and measurements highlight the complex nature of many archaeometric techniques, and indicate the potential problematical results obtained from applications where the experimental conditions are not well known.

Identifying the Sources of Artifacts

Determining the characteristics of raw materials obtained from quarries and recognizing the same attributes in archaeological objects allows an archaeologist to describe trading routes and interactions between groups of people. The simplest archaeological technique is to look at earth materials using a microscope. Such petrological analyses can be used, for example, to identify the rock types selected for production of prehistoric polished edge-ground axes. The texture and assemblage of minerals in stone tools can be compared with similar features in rocks at known quarry sites. This method was used to indicate complex prehistoric trading patterns in southeastern Australia. Hard, fine-grained hornfels from the Mt. William quarry was traded across hundreds of kilometers (McBryde, 1984). Similarly, Neolithic communication networks and boundaries were defined in England based on the petrological analysis of edge-ground hand axes (Cummins, 1980).

Subatomic particles can also be used to provide geochemical information about rocks and minerals to substantiate petrological and stylistic information about artifacts. For example, in the proton induced X-ray emission (PIXE) analysis of artifacts, high-energy protons are used to induce X-ray excitations from a range of elements. The measurement of multiple trace element abundances in artifacts, waste materials, and known sources can differentiate between quarries and can allocate artifacts to individual deposits. An example of this archaeometric method is the characterization of obsidian artifacts and sources for the investigation of the production, trade, and patterns of consumption of that natural resource in Melanesia. The systematic analysis of obsidian deposits and excavated flakes on New Britain have demonstrated that two exposures and possibly a third site supplied most of the obsidian for use as stone tools for more than 11 000 years (Summerhayes et al., 1993). Another analytical technique employing subatomic particles is neutron activation. Energetic neutrons, like the protons in PIXE, allow the measurement of elemental abundances in artifacts. Neutron activation analysis (NAA) has been used to source Late Neolithic and Early Bronze Age obsidian in Macedonia (Kilikoglou et al., 1996). Sources more than 300 km north and south of the archaeological site at Mandalo were shown to have provided raw obsidian for use as artifacts.

Neutron activation analysis has also been used to characterize steatite (soapstone) sources in eastern North America (Truncer et al., 1998). Relatively small quantities of rock can be analyzed using the NAA method to produce gamma rays from many elements, which are measured over four weeks. A wide range of trace and major elements, as well as rare earth elements can be measured after a single long irradiation in a flux of neutrons from a reactor. Statistical analysis of the large numbers of analytical measurements eases the burden of discriminating between quarry materials, and permits the identification or 'fingerprinting' of elements that are characteristic of each quarry.

The chemical and mineralogical characteristics of Australia ochers have been determined to discriminate between various sources and to confirm ethnographic accounts of long-distance trade. PIXE analyses have been used to characterize ocher sources in central Australia, with implications for defining trading networks and, delineating boundaries between Aboriginal populations (Smith et al., 1998). X-ray fluorescence has also provided major and trace element analyses, and Rietveld X-ray diffraction has identified the principal mineral phases for each known ocher source in southern Australia (Jercher et al., 1998). Ochers smeared on bones and objects have been traced to potential sources within geologically defined areas. The high degree of natural variability in ocher compositions makes such sourcing studies extremely challenging, so much so that it may be easier to exclude certain locations rather than identify specific sources.

Chemical analyses of other materials can also be used by the archaeometrist to provide useful information for the archaeologist. For instance, the minor ingredients in glass, especially the presence of lead, can be used to indicate the likely sources of glass production and the existence of trading networks. The ecclesiastical glass found at Koroinen, Finland illustrates how the tools of archaeometry provide insights into medieval manufacturing and trading processes (Kuisma-Kursula and Raisanen, 1999). Using X-rays generated from focused electrons in a scanning microscope and a beam of protons directed onto small glass fragments, the average chemical composition of the Finnish glasses were found to be remarkably similar to northwestern European glasses. The abundances of minor elements, particularly lead, sodium, and calcium, in medieval Finnish glasses are inconsistent with likely Russian sources, but match German and southern European glasses. The indication is that glass-making was not practiced in Finland at that time, but that supplies of colored glass for Finnish monasteries depended on trade links with Western and Central Europe.

Metallurgy

Unlike other geochemical sourcing studies that rely on finding significant archaeological variations in the intrinsic trace element compositions between different sources, the study of metal processing is far more challenging for an archaeometrist. Concentrations of trace elements vary between the ores and the processed metal, and complications arise because of the introduction of fluxes and refractory components. Lead isotope analyses, on the other hand, provide an alternative means for sourcing alloyed or leaded artifacts because the relative proportions of isotopes from ores to artifacts are not measurably affected by chemical and pyrometallurgical processes (Srinivasan, 1999). For example, thermal ionization mass spectrometry produces lead isotope ratios ($Pb^{208/207}$ and $Pb^{207/206}$) which were used to discriminate between known deposits of Indian lead ores and artifacts made from them. Matching artifacts to specific ore deposits using the isotopic ratios resolved contentious chronological issues based on art-historical criteria. Western Indian lead ores rather than local sources were found to have been used for brass in northern

India during the premedieval period, and also in lead and brass in southern India during the medieval period. Recycling of materials was also observed in Indian coins where lead isotope analyses of later bronzes fitted the trends established for earlier groupings.

Ceramics

Geochemical studies of pottery and porcelain have focused mainly on grouping complete objects or sherds into products that were either made locally or imported (*see* Ceramics in Archaeology). This has been done to establish or confirm suspected cultural links and trading associations between groups of people. Basic analyses of pottery sherds usually include determining the mineralogical compositions of the clay and temper to find out what specific materials were used and where a pot was made. This is done using petrographic and scanning electron microscopy. More detailed geochemical analyses may include the use of inductively coupled plasma emission spectroscopy, NAA, PIXE, or gamma-ray emissions. An example of one of these techniques is the confirmation of the extent of local production of fineware between the seventh and second centuries BC at a village on the Calabrian coast, Italy (Mirti et al., 1995). Often, distinctive patterns of elemental abundances are not readily evident in the large amount of geochemical data that is collected. Multivariate statistics are needed to separate disparate groups of pots, as in the case of Roman Samian pottery (Argyropoulos, 1995).

Paleodiets

Adaptation by people to changing environments and the transition in prehistoric societies from hunting and gathering to agricultural subsistence are topical themes in archaeology. These changes can be better understood through the measurements of stable carbon ($*^{13}C$) and nitrogen ($*^{15}N$) isotopes obtained from skeletal materials, and edible plants and animals (DeNiro and Epstein, 1978, 1981). Stable carbon isotopes were first used to study the introduction of maize into northeastern North America (Vogel and Van der Merwe, 1977). Their use is based on the observation that different groups of plants differ markedly in their isotopic compositions, and that therefore animals that live mainly on particular plants will have bones of matching composition. For example, studies of the paleodiets of people occupying southern Ontario, Canada (Katzenberg et al., 1995) and coastal New England, USA (Little and Schoeninger, 1995) have shown reliance on animal proteins rather than on maize or legumes during the Late Woodland period.

These examples of the applications of various analytical techniques reveal how archaeometry plays an important role in archaeology. Archaeometric methods are not used in isolation, but complement a range of other archaeological observations that build a more complete picture of the past. Archaeometry therefore provides a variety of tools that allow archaeologists to understand better human relics of the past.

Archival Methods

John Markoff, University of Pittsburgh, Pittsburgh, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The modern public archive dates from the era of the French Revolution. 'Archival methods' may denote the work of the profession of archivists in acquiring documents, classifying them, preserving them, providing them to users, and developing finding aids to assist those users. It also may refer to the work of historians with archival materials, the use of which has been a distinguishing feature of history as a discipline. Beginning in the late-twentieth century, new electronic information technologies were raising new questions about the future of archival methods in both senses of the term.

"[N]o documents, no history," declared Charles-Victor Langlois and Charles Seignobos (1898: p. 2) at the end of the nineteenth century as they begin their guide to historical research. They continued: "To hunt for and to gather the documents is therefore a part, logically the first part, and one of the most important parts, of the historian's craft" (1898: p. 2). They thus stated a methodological principle as well as a defining practice for a social science discipline. They offered a standard for progress: If more recent historians are in any way superior to those of the past it is because they have "the means to be better informed" (1898: p. 3). These means are the modern public archive, with its large and effectively cataloged collection, and the careful training of fledgling historians in the critical use of documents. In the early twenty-first century, historians still were far more likely than other social scientists to exchange tales of archival discomforts and delights and to guide their graduate students in crafting essays built around properly referenced primary sources. But new information technologies were blurring the distinction between archival and published sources, between primary and secondary sources, and between the methods of history and the methods of other social sciences.

Archives as Research Sites

Archives are the records of an organization's activities. The term is used both for the place those records are housed and for the body of records themselves. These records may have been produced by that organization or gathered by it. Such organizations include businesses, religious bodies, and government agencies, and we may stretch the notion to include the records of individual persons. Since the records were produced for the purposes of that person or organization, they tend to be organized for those purposes and not those of researchers. This means that archives are often difficult and sometimes impossible to use effectively without detailed knowledge of the organization in question. Researchers could hardly make much of the documents in some government archives without understanding the agencies that produced or collected the documents.

Archives, therefore, tend to be organized idiosyncratically. One archive may well differ from another not only in its classificatory categories but also in the extensiveness of inventories, catalogs, and other aids to research. There may be no list of individual documents, but just indications of more or less broad categories. The records of some country's regional or local governments may not be organized in a uniform manner. As a result of such challenges to a user's ingenuity and patience, a researcher may derive considerable pleasure from the sense of mastering an archive. By contrast, a researcher can get quite far in most libraries the world over by expecting to find an alphabetical catalog of authors and titles.

The Modern Public Archive

The linking of the modern practice of historical research and the modern public archive generally is dated from the French Revolution, but archives of some form are considerably older. Because states often have needed records of laws, tax assessments, and interstate treaties, state archives existed in antiquity. *Arkheia* is the Greek for an authority's records. It is probable that the invention of writing was spurred by the state need for documentation. So archives were part of the technology of state power, but they also could play an important role in the power claims of other social actors. In the European middle ages, lords and ecclesiastical institutions maintained records spelling out their privileges (etymologically: private laws). The possession of documents attesting to immunities from royal claims or the antiquity of claims over others (e.g., for seigneurial dues) was an important instrumentality of such privilege.

Early modern European states had their document collections, too, but these often were semiprivate, with individual agencies and even individual officials having their own archives. Steps toward centrally organized collections were part of the history of European statemaking; early centralizers included the Spanish archives of Charles V in 1545, the English State Paper Office in 1578, and the Archivum Secretum Vaticanum in 1611 (Favier, 1958: p. 24). But these were not accessible publicly, secrecy being as significant an attribute of the monarch's documentary collection as of the lord's.

The French Revolution launched the modern public archive. In France's villages, peasant attacks on the documentary collections of lords and monasteries testified to their continuing significance. Although the new revolutionary authorities promoted some archival destruction, the overwhelming thrust of their efforts ran in a very different direction. The separate collections of royal agencies, old regime corporate

institutions, and local powerholders were made public in two senses:

1. They were brought under state management and thereby opened up to systematic classification, not only in the National Archives housed in Paris, but in the uniformly organized departmental archives as well. This development greatly facilitated measures for preservation as well as cataloging. To organize the vast body of materials, some seized from lords or ecclesiastical bodies, the revolutionary state sought those with relevant experience, including those who had advised the lords or former Benedictines. With time, a modern profession of archivists formed around these tasks. France's first school for training this new corps, the Ecole des Chartes, was founded in 1821.
2. They were made accessible to the public. With exceptions for state secrets (a far more limited notion than before the Revolution) and the privacy of individual citizens whose identities might figure in state records, documents were to be made available for the scrutiny, and research, of French citizens. Archival documents were redefined from being primarily instruments of power, often private power, to aspects of the national cultural heritage. National archives took their place alongside national museums and national libraries as repositories of and as emblematic of a national heritage of which a respectable national government would claim stewardship.

In establishing France as the center of a reconstructed Europe, Napoleon had vast archival holdings transferred from Spain, Vienna, and much of Italy to Paris. In the wake of the French defeat, the recovery of other states' documents from France further strengthened the notion that a respectable modern state needed its own respectable modern archives. During the nineteenth century, and beyond, this increasingly meant that, like France's, other archives were going to be open to a far broader public than in the past (Favier, 1958).

Professional History

The historical profession that emerged in the nineteenth century combined a distinctive sense of evidence, a distinctive form of professional apprenticeship, and a distinctively organized intellectual product. This distinction was being developed in many places, but the model for the new professional history was provided in the writings and seminars of German historian Leopold von Ranke, beginning in the late 1820s (Novick, 1988).

1. Historical claims were supposed to be grounded in the best possible primary sources, generally those located in searching relevant archives. Historical knowledge would be disciplined, a notion that acquired important additional baggage as the German *wissenschaft* was transmuted into the English *science* as a description of the kind of learning produced by historical research.
2. Apprenticeship included practice in making something of primary sources in graduate seminars. To the extent that the seminar was seen as a sort of 'laboratory' (Novick, 1988: p. 33), the sense of history as a sort of science was augmented. Mastery would be further demonstrated by the completion of an original work dependent for its primary sources on unpublished, generally archival, materials. The budding historian would acquire not only the cognitive skills but also the character needed for archival labors. Historians needed to be "calm, reserved, circumspect; in the midst of the torrent of contemporary life which swirls about him, he is never in a rush." Those "always in a hurry to get to the end of something may manage to find honorable employment in other careers" (Langlois and Seignobos, 1898: p. 103).
3. Professionally respectable intellectual products consisted of books and articles whose factual claims, in principle, were verifiable from the primary documents to which the text would explicitly refer. The footnote to sources was a vital part of the prose of professional history (Grafton, 1997). Denoting the structure of reference – footnotes plus bibliography – as the scholarly 'apparatus' fostered rhetorical associations with science.

Important and diverse consequences followed from its characteristic methods for such a professionalized history:

1. *National specialization*. Historical specialties tended to be organized thematically around national histories because the archives were organized by states. Beyond linguistic familiarity, practitioners who had invested their energies in mastering one archive or set of archives found it advantageous to continue future work that would reap the benefit of those investments.
2. *Building national identities*. Partly as a consequence of this technology of history, and partly because states were supportive of such work, the writing of history became an important component of the very forging of national identities in the nineteenth and twentieth centuries.
3. *Focus on elites*. Because what was held in these state archives, by definition, were documents that had been of interest to state managers, professionalized history had a tendency to privilege the doings of states and other human practices of interest to administrators while paying lesser attention to other ways of exploring human experience.
4. *Geographically uneven attention*. Because the standards of professional history could best be attained where there were rich archival collections, cared for by skilled practitioners of preservation and cataloging, those parts of the world relatively well endowed in those regards were attractive to researchers who hoped to achieve professional advance. Such conditions meant governments (1) with rich documentary collections, (2) with the resources to support the preservation and cataloging of these collections, and (3) for which the French Revolutionary model of a public national archive as an essential component of a modern national identity had some resonance. Nowhere were these conditions better met than in France. Part of what had made France such an important center of innovation in professional history in the twentieth century was its marvelously organized archives. Countries (1) lacking extensive documentation, (2) having documents but lacking the resources or the interest in preserving them or organizing them coherently, or (3) with strong traditions of archival secrecy were all, in their different ways, more difficult terrain for professional historians.

Bureaucratized institutions other than states maintain archives as well, such as firms, universities, labor unions, social movement organizations, and hospitals, and these institutions have established their own practices of collection and preservation and their own rules of access for curious researchers.

5. *Marginalization*. The inverse of the previous points: social activities, social strata, and entire continents that either have been of little interest to producers of documents or have not developed such extensive and usable documentary collections have tended to be marginal areas for professional history. Historians interested in such subject matters have had to be methodologically innovative and sometimes have faced an enormous challenge for professional recognition.
6. *Eschewing explicit methodological discussion*. A professional socialization oriented to the careful scrutiny of the provenance of particular documents and the opportunities for knowledge and the motivations for falsification on the part of that document's author encouraged historians to delight in the particular. This was reinforced by the particularities of archives, knowledge of whose quirks was not readily transferable to other archives. Historians understood their own methods in large part as the location of useful texts in idiosyncratically organized archives in conjunction with the careful criticism of documentary sources. Such skills were acquired by experience and the patient application of a few readily assimilable critical rules of thumb. The capstone of training involved immersion in some idiosyncratic archive. Thus, as Langlois and Seignobos noted, "[t]o learn to distinguish in this enormous confused literature of printed inventories (to confine ourselves to such), that which merits confidence from that which does not, in a word to be able to make use of them, is a complete apprenticeship" (1898: p. 12). Historians therefore have directed far less of their intellectual efforts at methodological discussion and also have had fewer methods courses as part of graduate training than the other social sciences. In 1971, one study of graduate education commented that "methodology is the orphan of the history curriculum" (Landes and Tilly, 1971: p. 82); there is no reason to think that decades later things had changed significantly.
7. *Eschewing explicit theory construction*. Dependence on the fortunes of document survival, as Murray Murphey observed (1973: p. 148), is a major reason historians have been less prone than other social scientists to pursue a model of inquiry in which abstract hypotheses are formulated and then tested against available evidence. The unpredictabilities of archival research suggest instead the development of hypotheses in tandem with the exploration of data or in modern sociological lingo, the development of *grounded theory*. One often finds wholly unexpected documents sitting on a shelf. Theory building as an explicit and valued agenda therefore is less characteristic of people in departments of history than it is of those in sociology or political science and very much less so than in economics. Nor does a broad knowledge of history's big themes without a deep reserve of pertinent facts earn much esteem from professional peers. By way of contrast, graduate students in top US economics programs do not regard a deep knowledge of the economy as nearly as important to their professional futures as they do skill in mathematics (Klamer and Colander, 1990). One could not imagine graduate students in first-rate departments of history similarly downplaying the significance of a rich and concrete knowledge of some specific time and place in favor of mastering methodological or theoretical tools.

Working with Documents

The notion of 'archival methods' comprehends two rather different sorts of activity. First, there are the methods of collection, preservation, and cataloging on which documentary research in archives depends (Schellenberg, 1956; Brooks, 1969). Second, there is the work of historians (or others) with those documents. Essential to nineteenth-century notions of historical method was the 'criticism of sources.' Classic works of method, like that of Langlois and Seignobos (1898) provided a broad taxonomy of ways in which one document might be superior to another. For example, historians became skilled at considering the following:

1. possible errors of transcription in the reproduction of or quotation from ancient texts;
2. whether a document's author was in a position to reliably know that which was claimed;
3. what motivations that author might have for slanting a story this way and that;
4. how to select from among multiple documents the most credible account.

According to Langlois and Seignobos (1898: p. 131), historians need to cultivate an attitude they call 'methodical distrust': an author's 'every claim' must be suspected of being 'mendacious or mistaken' (p. 132). There follows a taxonomy of possible guises assumed by documentary deceit and error as a guide for avoiding the snares and pitfalls that might lead a researcher too easily to accept some statement as historical truth.

More recent reflection has pondered the forms of distortion that might exist in whole collections of documents, and recognizes along with Murray Murphey (1973: p. 146) that the survival of documents often has depended on fires, floods, and 'the concern of loving daughters.' If there is still much to be said for the formulation of Langlois and Seignobos that there is no history without documents, we may consider how it is that documents come to be available to the historian's scrutiny. We should consider (Shapiro et al., 1987) the following:

1. *Recording*. What social processes bring documents into existence? This includes taking into consideration what sorts of things are or are not of interest to states, economic enterprises, religious bodies, and other recorders of words. An increase in counted murders may indicate a greater interest of states in whether or not people are killing each other, for example. No doubt in many times and places social struggles in and near centers of government generate far more paper than those far away.
2. *Preservation*. What social processes destroy or preserve documents? We must consider not only the destructiveness

of war and fire, which often are random destroyers of texts and the wishes of loving (or hostile) relatives for preservation (or elimination), but also the existence of organized agencies for preserving or eliminating the records of the past. The existence of well-trained and dedicated archival professionals is more probable in some countries than others, more (we may speculate) in large urban centers, and more in relation to some subject matters (but which?) than others.

The study of the professional cultures of archivists would seem an important agenda for a self-critical history. Archivists are not simply neutral agents of an imperative to preserve and arrange. They play important roles in deciding what is to be preserved and how it is to be organized. Like other professionals, archivists develop a sense of collective identity, professional organizations, journals, codes of ethics, conferences, and disagreements. In the United States, for example, the Society of American Archivists organized itself separately from the American Historical Association in 1936 and its journal, *American Archivist*, was launched 2 years later. Archivists study the optimal conditions for the preservation of paper, including the challenges of the different papers in use at different times and places, and consider the potential erosion of moisture, light, and various temperatures. Archival culture tends to strongly favor keeping collections together, if they are to be kept at all, and in the original order, because that order may be an important clue to proper interpretation, but sometimes such principles have been violated in the interests of ease of use. Electronic records are a significant challenge to previously established practice (Schellenberg, 1956; Daniels and Welch, 1984; Bearman, 1991).

When economists, sociologists, or political scientists turn to archival sources to construct statistical series about social processes that extend over time and space, they are likely to encounter several problems. Some of these problems may be amenable to amelioration by statistical manipulation but others demand the kinds of analysis of sources that are characteristic of historians – and still others call for both in conjunction.

1. *Missing data*. Random document loss from moisture, fire, and the gnawing criticism of mice; deliberate destruction of troublesome records by those who might be embarrassed by some datum or data; and errors in filing by clerks all generate considerable missing cases in many potentially valuable data series. Statistical judgments about the appropriateness of completing the series by extrapolation and interpolation from surviving data may be complemented by the institutional knowledge that sometimes permits a researcher to find an alternative source for the same data.
2. *Changing definition*. Much data of interest to states is subject to changing definition and therefore many series of great interest to social scientists cannot be used intelligently without a study of those definitions. Crime, ethnicity, conflict, and poverty, for example, are all subject to considerable redefinition, both formally and informally. To make use of any long data series on crime, one would have to have acquired considerable knowledge of the changing interests of states in accurate data collection for different kinds of offenses. One also would have to know something of the changing mores that redefine actions as criminal or not (and which kind of crime they are). In addition, the boundaries of such administrative subdivisions as counties and municipalities often change, and a study of changing administrative geography often is an essential step on the way to some form of statistical correction.

Challenges to Professional Traditions

The last quarter or so of the twentieth century saw emerging challenges to such notions of research methods from several converging sources; these challenges were continuing into the next century. Because what was easy to examine with prevailing methodologies were those facets of human experience that had left traces in the documentary collection of states, the subject matters of professional history gave great weight to adults, men of weapon-bearing and income-earning age, dominant ethnicities, state politics, and dominant powers on the world scene. Those curious about other realms of human experience, including members of some of the underrepresented groups and places, were led to develop new methodologies.

To some extent, these involved innovative use of state archives, as in the mobilization of records of births and deaths to develop the new historical demography, a vital window on the past lives of ordinary people. Because average height in adults closely tracks childhood nutrition, the extensive records of height maintained by militaries has been used for new understandings of historical variation in wealth and poverty. Because wills are a good place to indicate wishes about how one is to be remembered, they have been used to track long-term changes in religiously connected commitments, and how these varied from place to place, over time, and among social groups. To some extent, innovation involved the use of new kinds of sources, as in the discovery of the value of visual materials for clues to the history of childhood or aging. Additionally, innovation involved extensive interaction with other social science disciplines, as in important interchanges with anthropology in the hope of getting a handle on people whose activities have left less easily pursued traces in the written records of states or in the importation of quantitative methods from economics, sociology, and political science (Rabb and Rotberg, 1982; Revel and Hunt, 1995).

Fueled by these trends, and fueling them, some professional historians became inclined to doubt the clarity and coherence of the entire project of a scientific history. This further eroded the rationale for a methodologically distinctive enterprise, thus opening the way for even further cross-disciplinary fertilization. But it also opened the way for a radical skepticism about any form of historical knowledge or inquiry whatsoever, which some dubbed 'postmodernism.' In the last quarter of the twentieth century, increased sensitivity to the ways in which the subject matter and methods of past historical research had been intertwined with social power was leading some to abandon the notion of any coherent historical truth altogether. But others held that such questions only showed that a historian's job was an engagement with more difficulties than covered in the meticulous account of Langlois and Seignobos and that

the deployment of new sorts of evidence on previously unresearched subjects simply made the past more interesting (Appleby et al., 1994).

Challenge and Opportunity of Electronic Information Technology

The new information technology becoming increasingly available at the end of the twentieth century was reshaping the ways in which archives were used and seemed certain to reshape what an archive was. These technologies were raising challenges to established archival methods, both in the sense of how archivists went about their tasks of developing and maintaining archives and in the sense of how historians made use of them.

1. *Cataloging could now be enhanced radically*. Particular items could be cross-classified in innumerable ways because electronic data files are not subject to the same sorts of space limits as a catalog's page or a card file, making it easier for researchers to find all information that is relevant. User-manipulated databases meant that users could sort through files according to the categories important to them, relieving them, to at least some limited extent, of the challenging burden of mastering the intricacies of the classificatory systems of particular archives. Because electronic information could be transmitted around the world at high speed through the Internet, researchers were becoming less dependent on visits to distant archives to have some notion of their contents.
2. *Reproduction of documents was immeasurably enhanced*. Age-old errors of transcription, inherent in hand copying of archival materials, were alleviated by the development of microfilming technologies and further reduced by photocopying. Both microfilming and photocopying technologies enhanced the labors of researchers from afar. But they also meant that archives and research libraries could duplicate their own scarce holdings and distribute them either to individual scholars or other research institutions. The potential of high-quality electronic scanners as input devices to computers was only at the very beginning of use in archival work at the beginning of the twenty-first century, but no one could doubt that the potential impact on research activities was going to be even greater in the future than it already had proven be early in the twenty-first century. Not only could a visiting researcher store large collections of source materials on a portable computer, but also such materials could be transmitted readily to far-off scholars. Digital files, moreover, often were searchable, which meant that one could, for example, look for how frequently certain terms or combinations of terms occurred in specifiable proximity to other terms or combinations of terms in very large numbers of documents. All this was opening up the prospect of electronic archives searched according to multiple criteria, further freeing researchers from the idiosyncrasies of particular catalogs. This also meant that as researchers became experienced with particular document collections, they could revise and refine their search criteria with ease rather then have to accept their own initially flawed classification scheme because they lacked the time to redo it. So a researcher initially did not have to be as erudite as previously before approaching a document collection, and beginning students could practice interpreting some of the same documents with which their teachers had made their reputations.

One could readily imagine digitized versions of the holdings of national libraries, made freely available to all, scholars and citizens, or even extending access beyond national frontiers. Or one could imagine separate research libraries participating in the common project of making their digitized holdings publicly available. Some European states were taking steps in these directions in the early twenty-first century (Darnton, 2010).

3. *Publishing*. New modes of electronic publishing seemed to some to have similarly important implications for the redefinition of professional scholarly standards. Robert Darnton has noted that a conventionally published book, for example, might omit its apparatus of learned footnotes and bibliography, but make them available to other interested scholars on a disk or an Internet site. One might speculate that this would lead to new forms of scholarly precision and richness (as scholars supplemented a basic text with footnoted references to sources, critiques of learned predecessors, methodological commentaries on sources or predecessors, annotated rather than bare-bones bibliographies, and even scanned copies of vital original documents). At the beginning of the twenty-first century, for example, it was technologically feasible for the learned footnote at the bottom of the printed page to be replaced by the electronic note in some online text in the form of a hyperlink to a scanned copy of the referenced text itself. Such superreferences actually would send the primary sources to the reader's screen or printer, rather than tell the reader in which place the source could be consulted (if that reader had the time and the good fortune to win a fellowship and to have a dean kind enough to grant leave). The capacity of historians to check each other's research against the primary sources would be greatly facilitated. Graduate students with no research funds to travel to document collections nonetheless could hone their critical faculties by studying the sources of prominent works without mastering archival idiosyncrasies. One could imagine future professional historians developing an ethical code requiring making electronic sources publicly available. This would raise again the question of whose responsibility it would be to make those materials useable (Darnton, 1999).

Conversely, the new technologies supported new ways of publishing traditionally structured books as well (including 'publication on demand') and books actually were continuing to increase in number (Darnton, 2010). And since the near-zero cost of transmitting electronic files somewhere multiplied the number of people with an opportunity to print them, archived paper, like archived books, did not seem to be decreasing. Archivists seemed much more ready than historians to define one of their central issues as deciding what to preserve.

The Future of Archival Methods

The new technologies were opening up what could be called *the electronic archive* (Shapiro and Markoff, 1998; Cohen and Rosenzweig, 2006). Databases, possibly accompanied by programs to facilitate use, once created, could be distributed readily, and even augmented by new scholars. But the archiving of electronic materials posed new challenges. First of all what was now technologically feasible was bumping into financial and legal obstacles in the form of copyright issues, the costs of digitization, and the hopes of profit-seeking enterprises to gain control of pieces of these revolutionary processes. Although the technology suggested an erosion of the distinction between a research library and an electronic archive, and scholarly journals in electronic form could nearly instantaneously be read around the world, those who controlled those journals were charging universities enormous fees for access, with that access to be restricted to properly certified members of the universities who paid. On the other hand, early in the twenty-first century, a variety of movements were calling for free access to all, not just academic researchers but beyond, and some electronic archives were organized on that basis. But even then, use was implicitly limited to those with access to appropriate hardware and software (Rosenzweig, 2011).

The proliferation of electronic materials was raising anew important issues of appraisal and accession, maintenance, and access, as storage media, software, and hardware platforms evolved, displacing previous technologies. Only a little way into the twenty-first century, the magnetic tapes and floppy disks of the near past seemed antiques and only some information stored on them had been transferred to newer devices.

Possible consequences for the future culture of historical research might include:

1. Blurring the distinction between research on primary and secondary materials as researchers grew comfortable with electronic archives built of many components that might range from scanned primary sources, quantitative data extracted from such sources, quantified data created from such sources by a researcher, and new variables or indexes added by a community of users.
2. Blurring the distinction between archival and published primary sources as information became available in electronic form, regardless of whether it was extracted from a book or found in an archival dossier.
3. Increasing attention to issues of representativeness of large bodies of data (and diminished concern for the traditional criticism of sources?).
4. Increasing research using primary sources by social scientists with the appropriate technical skill who were not employed by departments of history. User-friendly systems could mean that the level of technical skill needed might not be great. Whether this would mean more collaboration across disciplinary boundaries, or just more work using primary sources by people not having understood the institutional contexts of those sources, or both, was not easy to foresee.
5. Increasing use of archival materials by scholars, whether professional historians or not, who are not primarily specialists in the national history of the country from which the data are derived as it becomes easy for someone on the other side of the planet to use an electronic archive without having to master the particularities of traditional repositories of documents.
6. Increasing use of these resources by non academics, too, perhaps blurring somewhat the boundary between professional historians and history buffs. One could imagine as well the use in complex data-driven projects of a collaboration of amateurs and professionals, on the model of the ways in which professional astronomers were directing large numbers of interested volunteers in participating in sky mapping.
7. Increasing accessibility of materials vital to historical problems that cross national frontiers, as teams of scholars assemble relevant electronic archives.
8. Challenging the notion that an archive was a physical space, housing diverse important collections. An electronic archive need not be in a single place at all. One could imagine a 'distributed' archive, maintained by a consortium of physically distant places, all of which could be accessed from a computer screen by a user who might not even need to know where in the world each piece of information being accessed was physically housed.

One could envisage a possible democratization of the doing of history, as established scholars of more varied backgrounds, students at various levels, and nonacademics, too, joined in scrutinizing readily accessible primary materials. But one could also imagine a constriction, in which only those able to purchase computers, pay for subscriptions for commercially available data sets, and with access to one's own institution's expensive journals, could claim to be in the forefront of producing historical knowledge (Rosenzweig, 2011).

In such ways, the boundaries between history and the other social sciences may become less sharp than they have been since the emergence of the social science disciplines. These boundaries also were raising questions both exciting and troubling about how the pervasive yet evanescent structure of electronic materials might be preserved in useful form for the historians of the future, a challenge raised by what Roy Rosenzweig (2011: p. 7) called 'the simultaneous fragility and promiscuity of digital data.'

Archiving: Ethical Aspects

Abstract

Archiving refers to the process of transferring records from the individual or organization who created the material, to a repository for appraising, cataloging, organizing, preserving, and providing access to others. Social and behavioral science research engenders by-products that are worthy of archiving for a variety of future uses, including the furthering of basic and applied research, policy making, and the development and replication of effective intervention programs. Examples of such archive-worthy by-products are research data, their associated data collection instruments (questionnaires, interview protocols), and, more recently, intervention programs shown to be effective by evaluation research. Ethical issues occasionally arise in the archiving process. These issues typically relate to protecting the integrity of the selection process; protecting respondents' confidentiality; censoring potentially controversial or offensive material; the timing of the release of information to an archive; assignment of due credit to both original producer and archivist; the tension between fidelity and usability in the archiving process; and the ownership of the research and development by-products contained in the archive. Approaches to handling and resolving these ethical challenges are discussed.

Archiving By-Products of Social and Behavioral Research

Archiving refers to the process of transferring records from the individual or organization who created the material to a repository for appraising, cataloging, organizing, preserving, and providing access to others (National Archive of Australia, 2013; Pearce-Moses, 2005).

The social and behavioral sciences produce intellectual by-products at various stages of the research process that, if preserved and organized, could further basic and applied research, aid policy making, and facilitate the development and replication of effective social intervention programs. A variety of institutions preserve such materials. They include government archives, academic data archives and libraries, and specialized organizations in both the public and private sectors. Professional organizations of social science archivists and librarians have been formed to further the field.

The National Archives and Records Administration (NARA) is the US federal agency that preserves and ensures access to those official records which have been determined by the Archivist of the United States to have sufficient historical or other value to warrant their continued preservation by the Federal Government; and which have been accepted by the Archivist for deposit in his custody (44 U.S.C. 2901). Information about NARA's electronic records holdings (most of which are data files) can be obtained from the Internet site http://www.archives.gov/.

CESSDA ERIC, while not itself a data archive, is a large consortium for social science data archives across Europe. Established in the 1970s, the organization provides access through their catalog to information and links to nearly 9000 datasets stored at CESSDA archives throughout Europe. Those member organizations serve more than 30 000 social science researchers yearly, together deliver over 70 000 data collections each year, and continue to add more than 1000 data collections annually (http://www.cessda.org/).

The Inter-university Consortium for Political and Social Research (ICPSR) is the largest academic social science data archive. Founded in 1962 at the University of Michigan, ICPSR is a membership-based organization, which provides access to a large archive of computer-based research and instructional data in political science, sociology, demography, economics, history, education, gerontology, and criminal justice. More information about ICPSR and its holdings is available from http://www.icpsr.umich.edu.

The UK Data Archive, established more than 40 years ago, is the UK's largest collection of digital research data in the social sciences and humanities. The archive contains several thousand datasets acquired from the academic, public, and commercial sectors; and some datasets are available through Nesstar so that frequency counts and questions can be viewed online (http://data-archive.ac.uk/).

Norwegian Social Science Data Services, owned by the Ministry of Education and Research, is one of the largest archives of Social Science research data. Data are organized in four main categories: Individual Level Data, Regional Data, Data About Institutions, and Data About the Political System. Many of their data sets can be accessed, analyzed, and visualized with maps, graphs, and tables using Nesstar. In addition to direct on-line access, data can be downloaded and/or exported to preferred format (http://www.nsd.uib.no/nsd/english/index.html).

An example of private sector archives, Sociometrics Corporation was established in 1983. The company's primary mission is the development and dissemination of social science research-based resources for a variety of audiences, including researchers, students, policymakers, practitioners, and community-based organizations. Sociometrics has pioneered in the establishment and operation of topically focused data, instruments, and (since the mid-90s) program archives (http://www.socio.com): (1) *Data Archives*: collections of original machine-readable data from over 500 exemplary studies, many of them longitudinal, on the American family,

teen sexuality and pregnancy, social gerontology, disability, AIDS and STDs, maternal drug abuse, and geographic indicators; (2) *Instrument Archives*: the questionnaires, interview protocols, and other research instruments that were used to collect the data in the data archives; (3) *Program Archives*: collections of program and evaluation materials from several dozen intervention programs that have proven effective in preventing risky behaviors such as unprotected sex and drug use and in treating psychological and behavioral disorders, such as anxiety, depression, and aggression in children. These topically focused archives synthesize research in the field in one place; facilitate further research with the best existing data and accompanying instruments; promote data-based policy-making; and help service providers and practitioners use the insights gained from research (Card et al., 2007, 2006; Card and Kuhn, 2006).

Two professional organizations of social science data archivists and librarians are the Association of Population Libraries and Information Centers (APLIC) and the International Association for Social Science Information Service & Technology (IASSIST). APLIC's membership, consisting of both individuals and organizations, represents some of the oldest population and family planning agencies and institutions in the United States. IASSIST is an international organization dedicated to the issues and concerns of social science data librarians, data archivists, data producers, and data users. This unique professional association assists members in their support of social science research. The APLIC and IASSIST membership lists provide pointers to the various social science data collections housed all over the world (http://www.aplici.org/; http://www.iassistdata.org/).

Ethical Aspects in Archiving

The development of collections such as those contained in the above archives involves a series of decisions with ethical considerations and implications.

Protecting the Integrity of the Selection Process

Given the limited nature of resources allocable to archiving, how should the contents of collection be selected? Some archives sidestep this challenge by merely cataloging and warehousing archival material (e.g., data sets) donated to them by the field. While this procedure undoubtedly results in the lowest per-capita archiving cost, the quality of the resultant archival collection is uncertain at best. A better procedure is to set objective technical and substantive standards for inclusion in the archival collection and then actively recruit material that meets or surpasses such standards. Setting standards for inclusion can be problematic and contentious. Archivists and curators may often disagree on the future research needs in the organization or in the field. There are some general guidelines that can be used to minimize these challenges, such as making sure that the process used to make data selection decisions is transparent and accountable and guided by policy and legal requirments (Whyte and Wilson, 2010). Decisions about inclusion need to be based on a set of objective criteria for assessing the long-term significance of the research data, which should be developed and agreed upon by larger research communities, institutions, or experts in the field. These guidelines are unlikely to be static. Another challenge is that over time it is likely that standards and thinking in the field will change and inclusion criteria will need to be modified. For example, several years ago criteria for inclusion in an archive of effective behavioral interventions may have required that an evaluation of the intervention be conducted and that it should demonstrate continued behavior change at a 3-month follow up time period. However current standards require a 6-month follow up to demonstrate effectiveness and merit inclusion.

The previously described data and program archives at Sociometrics have worked with Scientist Expert Panels in establishing criteria for inclusion in various collections. For the data archives, the selection criteria are scientific merit, substantive utility, and program and policy relevance of the data sets comprising the collection. For the program archives, the selection criteria are documented effectiveness in preventing the particular social problem or disease (e.g., drug use, teen pregnancy, sexually transmitted disease, HIV/AIDS) or in changing these problems' risky-behavior antecedents (e.g., delaying age at first intercourse, increasing the use of contraception and/or an STD-prophylactic at first and every act of sexual intercourse, and abstaining from or reducing the frequency of drug use). Having established objective inclusion criteria, archive staff then work with their respective Scientist Expert Panels to identify and prioritize available data sets and intervention programs for inclusion in the collections. The end result is an archival collection with integrity and credibility.

Protecting Respondents' Confidentiality

Respondent confidentiality is one of the areas of greatest ethical concern, because once data are released for public use it is impossible to monitor use and ensure that confidentially is respected (ICPSR, 2012). Data archives often contain responses to sensitive questions, some of which, for example, ask respondents to admit to illegal, immoral, or 'private' behavior, such as abortion, premarital or extramarital sexual activity, mental illness, alcohol abuse, and drug use. How can the researcher's need to know (the incidence, prevalence, antecedents, and consequences of these social problems) be balanced against respondent's rights to privacy? This ethical consideration is most often addressed by stripping all archival material of information that could be used to identify individual subjects. Direct identifiers, e.g., name, address, social security number, and exact date of birth (often only month and year of birth are included in a public-use database), are typically easily removed. However indirect identifiers, variables that make unique respondents visible when paired with another, such as a participant with a low-incidence disability attending a rural school with unique characteristics, pose a greater challenge.

A problem arises when data holders want to strip the data set of key variables, such as those measuring the sensitive behaviors listed above, prior to placing a data set in a public use archive. This desire is motivated by the fear that such information could be linked to particular respondents by malicious, hardworking sleuths, even without the help of individual identifiers such as name, address, and so forth. Such censorship restricts the range of uses to which the data set can be put by

future researchers and archives typically make an active attempt to find alternate solutions. There are several solutions to problem. Indirect identifiers can be eliminated or modified by restricting the upper range of the variables, by combining or collapsing variables, or by adding random variation or stochastic error to the variable (ICPSR, 2012; Lawrence, 2010). Data donors typically consult with the archive producers to resolve concerns about identifiers. Other solutions focus on restricting use of the data. It is becoming common to require data users to sign a data use agreement that specifies a set of highly controlled conditions for the use of data prior to being granted access. This may be something as simple as signing a confidentially agreement and pledging to use the data only for research purposes.

However for datasets that have highly confidential material, more requirements are put in place. Many agreements require that the researcher provide an abstract of their research questions and explain why access to the restricted use file is required. They also have to outline a plan for safeguarding the data, and in some cases provide evidence of Institutional Review Board approval. Researchers may be given access to the data only for a limited time period, at the end of which they are expected in good faith to destroy them. There are instances when access to the most confidential data may require even more restrictions and users are typically only able to access those materials through a data enclave. This has meant that a researcher has to access those materials in a secure physical location. These enclaves allow access to the original data in a controlled setting and have physical security measures, such as video monitoring, key card entry, and controlled access; also, the computers housing the data are not connected to the Internet. Use is monitored by archive staff who confirm that materials are not removed and that analyses do not contain any confidential information. Virtual enclaves are replacing physical enclaves in some archives. Virtual enclaves are data portals that allow remote but restricted access to the application system and the restricted data. This access is monitored and the systems restrict users from emailing, copying, or moving files outside of the environment.

The original researcher should collaborate with the archive to determine the appropriate level of protection, aiming to allow the widest access to the data while maintaining confidentiality.

Consent for Data Sharing

While data sharing has long been encouraged and even required by research funders and a data sharing plan is often a required part of a research proposal, the original researcher often has not asked for the consent of the participants for sharing the data beyond the original research project. This can present an ethical dilemma for both the data donor and the archive. While requirements for consent vary by country and funder, this issue can be most easily addressed in the research-planning process and in planning for data sharing when developing study materials. For example, the Australian government has established the position that at minimum, consent forms should not preclude data sharing, e.g., by promising to destroy data; and more specifically, the National Statement defines three levels of consent for the future use of data that must be made clear to the participant: (1) Specific: which is limited only to the project; (2) Extended: which gives permission for the use of the data in future projects in the same general area of research; or (3) Unspecified: which allows for the use of data or tissue for any future research (NHMRC, 2007). If consent was not originally given for data sharing then the archive and the developer have to weigh the benefits of distributing the data against the problem of confidentiality and consent, with one likely outcome – the distribution only of data that is fully anonymous.

Special Considerations for Clinical Trial and Biomedical Data

While most social and behavioral science research projects and archives do not include clinical trial data, there are instances in which clinical trial or biomedical data may be included within a social science archive, such as the recently released Reaching for Excellence in Adolescent Care and Health (REACH) dataset (Adolescent Medicine HIV/AIDS Research Network, 2000; Pardini and Wu, 2011) which combines data on medical visits and laboratory results with access to tissue samples and a series of behavioral questions. REACH data were placed in a social science archive by the US National Institutes of Health specifically to expand the reach and analyses of the data to those beyond the medical sciences. The archiving of clinical trial and biomedical data bring additional ethical considerations. A majority of clinical trials are conducted by biopharmaceutical companies or clinical research groups and the data are typically not made accessible to other researchers or the public, and are rarely placed within a public archive. The lack of sharing within the scientific community has reduced the ability of scientists to validate the findings and examine the methodology of these studies. In many cases, (estimated at between 25 and 50% of trials), the results of these clinical trials are not published or made public (Ross et al., 2009, 2012). For those that have been published, in comparing published articles with trial protocols, 50% of efficacy and 65% of harm outcomes per trial have been shown to be incompletely reported and biased toward the reporting of statistically significant findings (Chan et al., 2004). This lack of transparency and availability of clinical trial data have led to calls for stronger data-sharing requirements. In response, in 2013, EFPIA (which represents the pharmaceutical industry operating in Europe) and PhRMA (the Pharmaceutical Research and Manufacturers of America which represents several US biopharmaceutical research and biotechnology companies) committed to Principles for Responsible Clinical Trial Data Sharing (PhRMA and EFPIA, 2013). Under this agreement, member companies commit to enhance data sharing with qualified researchers, share results with the patients who participate in clinical trials, enhance public access to clinical study information, and reaffirm their commitment to publish clinical trial results. However, rather than committing to archiving the data in a public archive it is the companies that determine who is a qualified to access the data, which again may limit the public availability of such data. One final consideration as clinical trial data becomes available to more researchers is the question of what to do with new results that may be found for participants in the study. In order to make the data available to researchers, the data is deidentified. This makes the conveying

of new results to participants nearly impossible, without the cooperation of the original researchers.

Censoring Potentially Controversial or Offensive Material in Collections

Intervention program archives occasionally encounter an analogous censorship-related challenge. For example, several of the effective programs selected for archiving by the Scientist Expert Panel of PASHA (Card et al., 2007) contain sexually explicit material that could be viewed as offensive and inappropriate by some individuals and communities. However, because these prevention programs are targeted at high-risk, already sexually active youth, the material could also be seen as appropriate, even necessary, to drive home relevant points. In addition, these programs, like other PASHA programs, meet the collection's inclusion criterion of demonstrated effectiveness in changing sexual risk-related behavior in at least one subgroup of teens. The decision was made to include the material without alteration or censorship but to publicize and disseminate the collection as an eclectic one, with different schools and communities being encouraged to replicate programs consistent with their own values, norms, and target populations. An accompanying database of program abstracts was developed so that both the approach and the content of the program packages could be perused, prior to requesting the program from the archive.

Timing of Release of Information to an Archive

Holders of data sets and developers of effective programs often, and understandably, want to reap some payoff from their professional investments by keeping the data or programs to themselves until they have published what they wish to from the data (or have tweaked the intervention program in several implementation cycles to their satisfaction). The ethical issue arises when this 'private' or 'proprietary' period of time stretches to what the field would view as abnormally long. This is especially true when the data were collected, or the intervention program developed, with government funds. Several US federal agencies are trying to forestall the problem by building resource-sharing ground rules into the original funding award document. For example, the National Science Foundation states that researchers with quantitative data should be prepared to place their data, in fully cleaned and documented form, in a data archive or library within a year after the expiration of an award (NSF, 2013). In contrast, the US National Institutes of Health is not as specific and instead expects those receiving large awards to share their data in a timely fashion with 'timely release and sharing,' defined as no later than the acceptance for publication of the main findings from the final data set. Ideally this solution gives the original developer the fair 'head start' his or her efforts have earned, while ensuring that the data collected with government funds will be shared with the field before it gets stale. However two primary issues remain; first, unfortunately the data sharing promises or pledges included in the funded grant proposal are typically not enforced and secondly, in many instances the timely release is based on the discretion of the researcher and many are reluctant to release the data, sometimes for more than a decade, until the data are outdated.

Assignment of Due Credit to Both Original Producer and Archivist

Data sets and program materials are typically received by an archive in a format that data developers and their colleagues find workable but one not yet suitable for public use. The archivist contributes significant additional value in preparing the database for public use. For example, with the approval of the data donor, inconsistencies in the database are eliminated, or at least documented. The documentation is augmented, both at the study level (describing study goals, sampling, and data collection procedures) and at the variable level (assigning names and labels for each variable; documenting algorithms for constructed scale variables). Occasionally, the variable and scale documentation is done using the syntax of a popular statistical analysis package such as SPSS (Statistical Package for the Social Sciences) or SAS (Statistical Analysis System), facilitating future data analysis. Archivists who prepare intervention program packages for public use make analogous contributions. Program materials are edited and 'prettified' for public use. User's Guides, Facilitator's Manuals, checklists, and handouts are created so that the package is implementation-ready in the absence of the original developer. In short, the archiving process is best viewed and executed as collaboration between original developer and archivist. Care must be taken to give due credit for the final product to all individuals, teams, and institutions involved.

Tension between Fidelity and Usability in the Archiving Process

The collaborative model is productive not only for assignment of due credit but also for joint resolution of the fidelity versus usability issues that occasionally arise during the archiving process. Others will be using the materials and have the opportunity to note errors in data or methodology, which leads to several ethical questions. Should obvious errors in the data base be corrected or only documented? Should resulting concerns about methodology be highlighted for those who acquire a dataset or program? Should original program materials that were found effective in the developmental site be altered when replication sites find them unclear or when the curriculum they present is based on out-of-date data? Issues such as these are best resolved on a case-by-case basis by the archivist and original developer, working side by side in collaborative fashion.

Ownership of the By-Products of Research and Development

The purposes and procedures of the archive accepting a donation should be made clear to the donor at the outset. It should be communicated to data donors that the research by-product they are donating toward is being put in a public archive whose main goal is the preservation of the resource.

Some archives also actively publicize and disseminate their holdings. In addition, as seen above, archives vary in the extent to which they work with the donor in 'upgrading' the material for public use. The donor should be informed in advance of what to expect along these lines. Issues of credit and ownership should also be agreed to before archiving work begins. How will professional credit for the collaborative product be allocated? Will the resultant product be sold to the end user (at cost or for profit) or given away? If the product will be sold for profit, will royalties be given to the original developer? If the product will be sold at cost, free, or discounted copies be made available to the original developer?

Conclusion and Looking to the Future

Social science research yields many by-products that, if properly archived, can be used to further future research, aid policymaking, and foster the development and replication of effective prevention and treatment programs. Several challenges, some with ethical implications, arise in the archiving process as it exists today. Many are resolvable with good will, a commitment to upholding the standards established by those in the research and archiving communities, and commitment to the public good on the part of both original developers and archivists. However, the recent discussions around data transparency of research findings and publications based on unreleased clinical data and social science data collected by companies, such as Google and Facebook, are likely to lead to new discussions around the ethics of archiving and the concept of archived data as being publically available. As we move into the age of 'big data' and collections of social networking data owned by corporations, discussions around confidentiality and privacy will probably evolve. The burden will fall to the community of scientists, archivists, and funding agencies to ensure that data sharing and data archiving for public use continues and is conducted ethically.

Arctic Archaeology and Prehistory

Owen K Mason, Institute of Arctic and Alpine Research, University of Colorado, Boulder, CO, USA

Abstract

The Arctic region in the northern hemisphere presented humans with dietary and temperature challenges and required a maritime sea mammal hunting or sea-ice adaptation. The colonization of this frigid and florally restricted environment occurred earlier than suspected, during the late Pleistocene *c*.27 000 years ago in northern Eurasia. In geographic terms, only northern Greenland, the coastal margins of Scandinavia, the Taymyr, and Alaska lie beyond the Arctic Circle. By contrast, sustained settlement of the North American High Arctic and Greenland did not occur until late in the Holocene, *c*.5000 years ago. Complex whaling societies developed in Bering Strait by 2000 years ago. For the most part, Arctic archaeology is synonymous with a single Mongoloid population, the Inuit (formerly Eskimo) who still dominate the region from Alaska to Greenland. A brief incursion between AD 900 and 1400 by the European Norse was renewed by Danish colonists in the early eighteenth century and continues to the present.

The Arctic region in the northern hemisphere presented humans with dietary and temperature challenges and required a maritime or sea-ice adaptation. The colonization of this frigid and florally restricted environment occurred earlier than suspected, during the late Pleistocene in northern Eurasia. In geographic terms, only northern Greenland, the coastal margins of Scandinavia, the Taymyr, and Alaska lie beyond the Arctic Circle. However, sustained settlement of the North American High Arctic and Greenland did not occur until late in the Holocene, *c*.5000 years ago. For the most part, Arctic archaeology is synonymous with a single Mongoloid population, the Inuit (formerly Eskimo) who still dominate the region from Alaska to Greenland. A brief incursion between AD 900 and *c*.1400 by the European Norse was renewed by Danish colonists in the early eighteenth century and continues to the present.

Ecological definitions of the Arctic, e.g., the absence of trees, typically extend its limit considerably south of the astronomical Arctic Circle at 66° 33″ N. latitude (Nuttall and Callaghan, 2000). The extent of perennial sea ice and the 10 °C July isotherm are convenient boundaries for the Arctic region. Several marine mammal species, seals, polar bears, walrus, and whales are ice-obligate; distributions that are synonymous with the Arctic. Several diverse geomorphic zones define the North American sector of the Arctic, broadly, the western consists of the mostly low and unglaciated coasts about the Bering Strait and Yukon River delta, northern Chukotka and the northern slope of Alaska and the Yukon, and Northwest territories. The treeless zone of Alaska extends far south to 50° N, which includes the lengthy volcanic arc of the Aleutian Islands. To the east, extensive Pleistocene glaciations sealed, compressed, and carved the ancient cratonic rocks of the Canadian Arctic Archipelago and maritime Greenland. The limits of the Arctic track sea ice distribution into Hudson Bay and as far south as Newfoundland. As sea ice retreats and temperatures rise, the boundaries of the ecological Arctic and its inhabitants shift across time and space; the Arctic sea ice of the Little Ice Age or Neoglacial was far more extensive than that of the anthropogenic twenty-first century.

Archaeological research commenced in the Arctic as a byproduct of eighteenth and nineteenth century colonial or commercial enterprises by Russians, Danes, and Americans (Collins, 1984; Fitzhugh et al., 2002). The sophisticated clothing and hunting technology of the indigenous Inuit impressed explorers and naturalists who subsequently sought its origins by archaeological methods. Archaeological investigations in the Arctic were conducted as early as 1906 as a colonial project by Danes, Americans, and Russians, following several centuries of interaction between Europeans and Inuit during which ethnographic observations were detailed, focusing on material culture, linguistics, and kinship. Anthropology largely matured as a discipline in the Arctic as early cultural anthropologists like Franz Boaz and Diamond Jenness conducted pioneering field work among the central Eskimo of Arctic Canada and Alf Porsild and William Thalbitzer did similar research in Arctic Greenland (Collins, 1984). High regard for the technological achievement of Inuit peoples among anthropologists, explorers, and colonial administrators led to the development of several Danish theories of Inuit origins by Hinrich Rink and Hans Steensby who proposed an interior source, followed by a descent along north flowing rivers through the forest into the treeless Arctic.

Although isolated objects were collected by naturalists and ethnographers such as the Swede Otto Nordenskjold in Siberia and American John Murdoch in Alaska in the late 1870s, the first large-scale effort at archaeological collection, was undertaken by Native laborers, directed by Vilhjálmur Stefánsson at Barrow, Alaska, in 1909, and produced evidence of an elaborate harpoon technology, often decorated. Systematic archaeological investigation started around 1925 in both the eastern and western Arctic. In the east, the Dane Therkel Mathiassen (1927) excavated in the central Canadian Archipelago and described a Thule culture, with an inferred age of 1000 years based on an extrapolated rate of uplift of formerly glaciated landscapes. In the western Arctic, Diamond Jenness inaugurated archaeological research *c*.1925 along the Bering Strait by discovering an 'archaic' Bering Sea culture on the Diomede Islands. Similar elaborated and decorated harpoon heads were uncovered in the late 1920s and early 1930s in large mounds on St. Lawrence Island and northern Alaska by Collins and his colleague James Ford. Research intensified in the Interwar Period, with most of the large coastal mounds investigated by

1945. The discovery of the Ipiutak site at Point Hope in 1939 revealed hundreds of houses and burials and stood for a generation as an unexplainable anomaly (Larsen and Rainey, 1948; Mason, 2006). Superimposed houses and occupation layers at a few sites (e.g., Onion Portage (Dumond, 1987)) allowed the construction of relative cultural chronologies that led to inferences of a rather limited prehistory of several thousand years, constrained by geomorphic factors such as continental glaciation and sea level history in regions transgressed by rising sea levels in the late Holocene. Since 1945, several generations of grant and government funded archaeologists and cultural resource managers have elaborated and refined the basic chronology. Research incorporated modern theoretical and methodological advances after 1970 under the aegis of research institutions such as the Smithsonian, Danish National Museum, Museum of Oriental Art (Moscow), Canadian Museum of Civilisation, the state universities of Wisconsin and Washington, as well as private schools like Brown University and Bryn Mayr. Interdisciplinary research commenced in the Aleutian Islands in the early 1960s (Dumond, 1987).

Modern humans, hunting extinct fauna, reached the 60th parallel in Europe and in Siberia during an interglacial of the Upper Pleistocene, *c*.42 000–35 000 years ago. Hunters in Yakutia were harvesting mammoth, woolly rhinoceros, caribou and horse at the Ikhine site around 34 000 years ago. For eastern Eurasia, humans ventured close to the Arctic Ocean during the Last Glacial Maximum, *c*.33 000–31 000 years ago. Extensive research by Pitulko (2012) at the Yana site shows a sophisticated bone technology and a highly developed linear aesthetic centered on pendants and zoomorphic figures.

A major hiatus in Arctic occupation followed after 25 000 years ago, the peak of the Last Glacial Maximum; apparently intense cold or decreased fauna restricted human population or interest in the North. Continental glaciation capped the Canadian and Greenlandic sectors, while the Bering Strait region was exposed as the subcontinent termed Beringia. The first evidence of a cross-continent Eurasia to North America migration occurs in the late Pleistocene, preserved in the Subarctic of Siberia and Alaska, *c*.14 000 years ago at well-dated archaeological sites in central Kamchatka and in the Nenana and Tanana valleys (Hoffecker and Elias, 2007). Direct evidence in the Bering Strait is assumed to lie on the then exposed, but now flooded, continental shelves.

The deglaciation of the Arctic Archipelagos proceeded over several millennia, after 10 000 BP, the onset of the Holocene. As polar bear and sea mammals recolonized the new lands, humans followed: first into the New Siberian Islands off of the Taymyr Peninsula, *c*.9000 years ago, where a distinctive microlithic technology was employed to dispatch bears and walrus (Pitulko, 2003) Canada and Greenland did not witness a similar early Holocene peopling, although the biota were present, based on ^{14}C dated whale bone on uplifted beaches. In the eastern zone, evidence of a late Pleistocene entry into northern Labrador is inferred from the transport of the distinctive Ramah chert into New England.

In the western Arctic, evidence of maritime hunting from *c*.9000 years ago was preserved on several islands, including Anangula and Unalaska in the eastern Aleutians. The origins of these populations remain uncertain (Knecht et al., 2001). Early researchers argued that the Anangulans relied on an exclusively unifacial technology, whose origins lie to the south. Subsequent researchers noted continuity with other microblade technologies along the Alaska Peninsula and onto Kodiak Island. Absent physical evidence, the use of boats, and the hunting of sea mammals are inferred from geomorphic setting and lithic technology.

A variety of technological innovations were required for sustained and successful Arctic adaptations. These included: a sophisticated repertoire of maritime craft (kayak and umiaq), dog traction, tailored skin clothing, snow goggles, as well as specialized sea mammal hunting equipment. The antiquity of this technology is not yet established, although its use is well authenticated following the development of large mounds in the last millennium BC. Architectural innovations were more limited but include subterranean houses as well as portable tents.

Around 5000 years ago, the coasts of northern and western Alaska witnessed their first intensive occupation, associated with a widespread and distinctive technology renowned for its fine and minute flint knapping. This Arctic Small Tool tradition (ASTt) was first encountered by J. Louis Giddings in 1948 at Cape Denbigh on the eastern shore of Norton Sound. The ASTt technology consisted of very small flaked stone cutting objects that were inset into bone hafts. ASTt peoples were predominantly sea mammal hunters and relying on the atlatl, or spear-thrower, and the toggling harpoon head, as well as on kayaks for transport.

Climate was possibly warmer at this time, which facilitated a rapid expansion of ASTt people from the Bering Strait into the interior and to northern Greenland. ASTt people ascended the rivers and mountains of northern Alaska, especially the Brooks Range, often using lakes to spear disadvantaged swimming caribou. Camp sites at Onion Portage are dated *c*.4200 years ago (Dumond, 1987). The Alaska migrants to the High Arctic must have already developed a complex marine hunting technology, including the bow and arrow as well as the kayak. At the frozen Greenland Qeqertasussuk site, Bjarne Gronnow (in Morrison and Pilon, 1994) obtained well-preserved wood, including kayak, bow and arrows, lances, spear and atlalt parts, barbed dart and leister points from a Saqqaq occupation around 4500 years ago (cf various in Morrison and Pilon, 1994). Subsistence relied on migrating harp seals and walrus, as well as ringed and bearded seals, fish (cod and char), birds, and several types of small whales both hunted and scavenged. The taking of the great auk at more northerly regions indicates a climatic warming. By 4000 years ago, the Saqqaq peoples had settled along western Greenland coasts, with a transition into the succeeding Independence I culture. Both Saqqaq and Independence I ASTt peoples were absent from Greenland after 800 BC, when another group makes its appearance from Arctic Canada. From the Canadian Archipelago to the Hudson Strait, another culture closely related to the ASTt, known as pre-Dorset, arose around 1200 BC. Pre-Dorset culture was also marked by distinctive harpoon heads, subsistence pursuits, and architecture (Maxwell, 1985).

The southern expansion of sea ice during the Neoglacial also allowed the ASTt to extend into the eastern Aleutian Islands (Knecht et al., 2001). Occupied *c*.5000 years ago, Margaret Bay on Unalaska Island is remarkable for its bone

artifact preservation and for a >1 m thick shell midden, with a diverse marine fauna. The bone objects include multiple barbed, tapering, cruciform stem, nontoggling harpoon darts – a very distinctive technology occurring for the rest of the Holocene in southern Alaska. Throwing board pins establish the use of the atlatl. Although harbor seal predominates, northern species were apparent on Unalaska in the mid-sixth millennium BP, most prominently polar bear and walrus that are not present today. Apparently, Margaret Bay was occupied during a cooler episode – archaeologists are still uncertain whether the site was the result of wandering northerners or whether southerners innovated due to the pressure of colder conditions and thrived beyond all measure, thus leading to a northward migration as the cold ceased. Although no boat pieces are known, it is inconceivable that maritime hunting on a large scale could have been entertained in the absence of watercraft.

In northern Alaska, the late Holocene development of sedentary and complex societies closely tracks the distribution of Pacific walrus, as Henry Collins first hypothesized in 1940. As a consequence of its cultural uses (cordage, food, skin for boat coverings, bone, and ivory for tools), walrus enhanced the role of women in skin work and fostered artistic production. Walrus hunting was possibly a precursor to hunting whales. By 5000 years ago on the prominent haul-out on Round Island in northern Bristol Bay, people were using spears tipped with notched bifaces. Several sites from Bristol Bay, Kotzebue Sound, and Wrangel Island parallel the distribution of walrus. This lithic technology was termed Chukchi Archaic by Mason and Gerlach (1995) and bears close resemblances to the technology of the first complex societies along the Bering Strait.

Around 4500–3500 years ago, a settling in of dramatic proportions occurred along the coast from the eastern Aleutians to the southern Alaska Peninsula (Dumond, 1987). In the next millennium, to 2500 years ago, a similar situation prevailed along the Bering Strait, especially on St. Lawrence Island, Cape Dezhneva, and the Diomede Islands (Fitzhugh and Crowell, 1988). This period was colder and stormier with enhanced upwelling, heightened nutrients, and marine productivity that benefited people across the region and led to a population surge. Following 2500 years ago, most cultural mounds added meter upon meter of height at critical and useful locations, occasionally accompanied by human bodies purposefully (or accidentally) interred. In addition, dedicated cemeteries appear in great numbers across the Aleutians and at the Bering Strait, providing evidence of sedentism. In northern Alaska and Chukotka, three cemeteries inferred to date to around 1000–500 BC contain high status graves with evidence of warfare and long distance trade (Mason, 1998; *see* Conflict and War, Archaeology of: Behavior and Social Organization) and in Chukotka, the first evidence of bronze in the far north.

Shell and bone middens, often forming elevated mounds, are ubiquitous on the Aleutian Islands – most with extensive viewsheds to sight prey and enemies. To further avoid attack, precontact sites were rarely at river mouths (McCartney, 1984). Many middens, extending 4 m in depth, contain whale bone houses and debris, with evidence of warfare, such as distinctive multi-barbed arrow points, increasing toward the more recent levels. Like most island dwellers across the Bering Sea and adjacent Gulf of Alaska, the lack of land mammals led to an increasing reliance on marine resources and required watercraft, the kayak, and the umiaq.

The two site types – mounds and village aggregations – reflect larger populations on the southern Alaska Peninsula from Port Moller north, and adjacent islands including the eastern Aleutians, Shumagin, and Sanak islands (McCartney, 1984; Maschner, 1999). The archaeological mounds formed after 4500–2700 years ago in core areas adjacent to hot spots for walrus and seal along Bering Strait and north, or along salmon streams to the south. Aggregations of abandoned houses number in the hundreds and a sophisticated harpoon technology supported fisheries based on cod or salmon, as ecologies shifted with colder or warmer sea surface conditions. The distributions of distinctive artifacts (such as harpoon heads and arrowpoints) track several migrations: (1) *c.*3000 years ago, a south to north trajectory by Choris peoples and (2) the Thule migration from west to east across Arctic North America and Greenland. Common stone building techniques and aesthetic ideas have led some archaeologists to posit direct genetic links between Aleutian islanders and the later, widespread Dorset culture.

The effects of climate on eastern Arctic peoples are difficult to gauge. Gaps in settlement history during cool episodes associated with Neoglacial expansion have fed interpretations of climate-induced retreat, especially in northern and central Greenland. Across the eastern Arctic from Greenland to Arctic Canada, *c.*1000 BC, the ASTt societies developed *in situ* from Saqqaq to pre-Dorset and Dorset. There were profound similarities in cultural practice over time among these archaeological cultures, especially in the use of a distinctive mid-passage house with upright slab hearths and side-notched spear points and side scrapers. A distinctive harpoon head, 'Tyara sliced' has traditionally marked the spread of Dorset culture around 600 BC. Sea mammal hunting sustained most societies, with core regions in Baffin Island in the Foxe Basin and along the Hudson Strait, where early Dorset occupations date to 800 BC. The major sites are Igloolik, the Tanfield site, and Arnapik (Maxwell, 1985).

From 500 BC to AD 1200, the Dorset culture was distributed across northern Canada, Greenland, and south to Labrador and Newfoundland. Early Dorset houses were square with short entry ways (Maxwell, 1985). Late Dorset societies were socially complex, occupying large multi-hearth stone structures that some archaeologists envision as theaters for shamanic performance. A repertoire of wooden masks distributed at many locales suggests performance. Dorset art is complex and figural, and is attributed to shamanistic beliefs, as revealed by its X-ray skeletal motifs and the portrayal of dangerous beings, including humans (Maxwell, 1985). Around 3000–2500 years ago, across much of mainland and southern Alaska, sizable villages of the Norton tradition developed at the mouths of salmon bearing streams, marked by the use of slate, net sinkers, the adoption of Siberian-derived ceramics, and dedicated mortuary precincts (Giddings, 1964; Dumond, 1987). Some researchers link the onset of sedentism with the Neoglacial and increased productivity. Larger villages, likely consisting of dozens of houses, are common east of Nome. Southern, possibly Aleutian influences are witnessed in its initial Choris phase by labrets and barbed harpoon heads. In

lithic technology, commonalities in flaking place both Choris and Norton in a line of descent from ASTt. The fate of the Norton villages is problematic; in the Yukon delta and to the south, a lengthy transformation into modern Yup'ik peoples occurred, with an intrusion and the influence of Inuit peoples of northern Alaska occurring around AD 700–900. In northern Alaska, Norton evolved into Ipiutak, an ally of Bering Strait societies, possibly with some influences from the interior.

Contemporaneous with Norton, the archaeology of the core regions adjacent to the Bering Strait hotspots witnessed a radical conceptual and socioeconomic breakthrough as early as 400–250 BC (Fitzhugh and Crowell, 1988). In Old Bering Sea (OBS) and Ipuitak societies, virtually every artifact was overlain with formalized circle and dot motifs and as figural and facial representations was crafted, both of animals and humans. Three principal artistic styles are defined: Okvik, OBS (I, II, and III), and Ipiutak (Collins, 1973; Dumond, 1987; Fitzhugh et al., 2009). Cemeteries from the earliest cultures contain evidence of a few high status individuals, both men and women, some of whom engaged in long-distance trade in obsidian across the Bering Strait (Mason, 1998). Art appeared earliest along the northern Alaska coast, at Battle Rock, and north of Cape Krusenstern probably dating to the Norton phase (*c*.500 BC) and was spare and linear, apparently decorative in function. The radical shift is that animals and humans were portrayed in Okvik and Old Bering cultures; common subjects include animal faces, mother and child, as well as submissive males (Collins, 1973). Ethnographic parallels can be read so that the designs represent cosmologies although sympathetic hunting magic, and the strong function to ward off evil (cf various in Fitzhugh et al., 2009). The objects reflect that only a few shamans had power and were a symptom of a society in need of power; some archaeologists interpret Ipiutak mortuary art as part of a crisis cult, related to adverse climatic conditions (Mason, 2006, 2009).

The OBS culture occurs on both north and south Chukotka coasts, on the Diomedes, and on St. Lawrence Island. It had only a limited distribution in Alaska, with isolated finds from the Yukon Delta to Pt. Barrow. Prevalent between AD 200 and 900, the distinctive art styles of OBS and Ipiutak delineate several allied societies that traded and engaged in warfare with each other or with an external enemy, possibly the Birnirk societies of the more northerly Chukchi Sea (Mason, 1998). Evidence of warfare is unequivocal and includes distinctive weaponry (daggers and spear heads) as well as human bone impaled with bone points. Mortuary contexts record specialized leaders and shamans. Although the dating of the two art styles is still in development, it appears that the most elaborate art was produced within a few centuries between AD 600 and 900 (Mason, 2006), part of a crisis cult associated with anomalous weather that stressed societies across both the western and eastern Arctic. Iron and obsidian were used for cutting or engraving bone and indicate the distant extent of extraregional exchange systems. The iron is metallurgical, not meteoric, but evidence of iron use by OBS peoples is restricted to two burins from Ekven and one from Uelen, and one large axe from St. Lawrence Island. Iron burins also occur at three sites in the contemporaneous Ipiutak culture, which dominated the Alaska mainland (Fitzhugh and Crowell, 1988). Obsidian was obtained from considerably farther south, in Kamchatka. The role of dogs in transportation and diet remains uncertain although small breeds were kept, possibly for dietary and sacrificial purposes, based on the number of dog bones and the treatment of their skulls. On the other hand, sleds for ice hauling are evident from the numerous ivory runners and shoes recovered.

Between AD 800 and 1000, a drastic shift occurred in nearly all Arctic societies (Dumond, 1987; Mason, 2009; McGhee, 1984), with the crisis cults, like Dorset, Ipiutak, and Kachemak disappearing and new whale-based societies gaining momentum. These changes possibly represented new ethnic amalgams, if not new peoples (Mason, 1998). The Thule culture originated along a wide margin from northern Chukotka to northern Alaska (Dumond, 1987; McGhee, 2001). Innovations in sea mammal hunting (drag-float apparatus) and nautical technology co-occurred with architectural shifts and mortuary patterns that favored subfloor burial over cemeteries. A de-emphasis of decorated ivory co-occurs in Alaska with decline in iron supply and the more extensive use of jade, amber, and slate, possibly representing a revaluing of aesthetic frameworks. In northern Alaska, status differentials in burials are rare, as are large village sites. The long-standing belief among archaeologists is that the pan-Arctic migration of Thule peoples was catalyzed by high populations stressed by the unfamiliar warmth of the Medieval Climate Anomaly. Very little data support this scenario and proxy climate show colder conditions *c*.AD 1000 precede the movement from Alaska to the east. The Thule culture continued to adjust to the cooler climates of the Little Ice Age, with increasing success in whaling within the core regions of central Canadian Arctic, in the Mackenzie delta and in the northwest Alaska (McGhee, 2001; various in Arneborg and GrØnnow, 2006; Maschner et al., 2009). In the latter area, a series of large villages dominated, with populations of several hundred at Point Hope, Point Barrow, and Cape Prince of Wales (Dumond, 1987; Maschner et al., 2009). Seasonal trade fairs were established at several centers, including the Colville River, Barter Island, Wales, Kotzebue, and the Anadyr, possibly as early as AD 1400, with Russian trade goods entering the western Arctic in the seventeenth century, if not earlier. Population increases were associated with increased warfare, intensified by the introduction of East Asian military practices, especially slat armor.

The well-documented migration of Thule people resulted in an occupation throughout Greenland and the Canadian Arctic, including northern Quebec, eastern Hudson Bay, and as far south as Labrador. This migration commenced in the thirteenth century AD and occurred in several stages (GullØv, 1997; Arneborg and GrØnnow, 2006; McGhee, 2001; Maschner et al., 2009). A complex relationship existed between in-migrating Thule and the preceding Dorset peoples, possibly one of intermarriage. The two cultures were contemporaneous between AD 1200 and 1300. Artifact forms, especially harpoon heads, show contact, but no firm evidence of warfare exists and slat armor is not found in Arctic Canada or Greenland (Maschner et al., 2009). Thule settlements were typically composed of several houses, and are well-known for their use of whale bone for structural elements and flat rock slabs for flooring and low rock walls.

Thule peoples thrived during the Little Ice Age and were accomplished whalers, employing harpoon heads similar to those of western Alaska. Thule whale hunters specialized in the capture of 7–11 m animals, according to faunal data interpreted by McCartney (1995; *see* Zooarchaeology). Thule life ways and whaling techniques are illustrated in carvings on whale bone. The Thule culture forms the material substrate of the late prehistoric and contact Inuit who were encountered first by the Norse *c*.AD 1000 and subsequently by the Danes and British, commencing with Martin Frobisher's landing on Baffin Island in 1576. The archaeology of the Thule culture was launched by Therkel Mathiassen (1927) and the Fifth Thule expedition of the 1920s.

The late tenth century AD also witnessed the colonization of southern Greenland by Norse peoples from Iceland and Scandinavia (Lewis-Simpson, 2002). The Greenlandic colonies represent a total break with the marine-centric subsistence economies that prevailed across the Arctic. The Norse did attempt to rely on transhumant pastoralism of sheep, goats, and cattle; nonetheless, seal and other marine animals were a significant part of the diet. Two principal settlements, Western and Eastern, were situated on the southernmost shore of Greenland, within the inner fjords. Houses and churches were constructed of stone and sod, with animals kept within the houses. The Greenlandic Norse maintained close economic and social ties with Iceland and Europe, communicating with Church officials until the early fifteenth century. The Norse successfully transplanted stone architecture and woven woolen clothing in distinction to skin clothing of their Inuit neighbors, with whom iron was transferred intermittently. The abandonment of the Norse settlements remains uncertain; various scholars attribute their demise to adverse climate change, adverse pasture management, plague, or excess taxation. In the early eighteenth century, Danish colonists returned to Greenland and established villages along its southern and western shores; archaeological studies of such remains provide a record of European trade items and distinctive architecture.

European contact with Native societies in the western Arctic started in the late seventeenth century AD as Russian fur traders entered eastern Siberia and supplied tobacco and other goods to local trade fairs along the Chukotkan coast (Vaughan, 1999). A brutal military campaign reduced the Koryak and Chukchi peoples and intensified militarism through the Bering Strait region. The Russians established only two settlements, on the Kuskokwim River and at Saint Michael, north of the Aleutian Islands, preferring to employ Aleuts to harvest fur seals on the Pribilof Islands. Capt. James Cook was the first European to map northwest Alaska, reaching as far as Icy Cape in 1778. The British under Capt. William Beechey were the first Europeans at Barrow by 1826. Only two Russian expeditions ventured along the coast of northwest Alaska, that of Otto von Kotzebue in 1816 and that of I. Kasevarov in 1838. Following its transfer to the United States, American whalers and entrepreneurs established trading and whaling stations at various communities on the north coast of Alaska (Vaughan, 1999). Native populations were decimated in the nineteenth century by a combination of epidemic disease and the effects of overharvesting of whale. Archaeological and ethnohistorical research has established the early to mid-nineteenth century introduction of firearms, metal and ceramic cooking equipment, and other dietary changes such as the use of flour and alcohol. The later nineteenth century also witnessed drastic changes in mortuary practices, a shift in housing from subterranean to above-ground frame structures, and in the adoption of wood and coal-fired stoves. Metal tools, especially for woodworking, cooking, whaling, etc. replaced stone tools after 1867. Due to overharvesting by Euro-American whalers, Native whaling nearly vanished by 1920, but was successfully revitalized after 1940. The introduction of the rifle after 1870 led to Native overhunting of caribou. The U.S. territorial government response to this crisis by Education administrator Sheldon Jackson led to the introduction of reindeer and a European herding culture. Christian missionizing by various sects led to the construction of churches and the establishment of bounded cemetery precincts. In the twentieth century, Euro-American/Canadian concepts of settlement design and housing took precedence with the establishment of schools and stores in central places – a process that led to the abandonment of many smaller camp sites. The absorption of Native communities into the global system continues in the twenty-first century, tempered by the persistence and resilience of communities in the face of this onslaught and the increasingly dire effects of global anthropogenic climate change.

Abstract

The Arctic and its peoples have intrigued southeners for millennia. Currently, there is heightened interest in the North due to its resource potential and the pronounced effects of climate change. This article focuses on a discussion of 'traditional' indigenous cultures in the Arctic in the nineteenth to the twentieth centuries. The material will be presented along topical domains: ecology and economy, social and political organization, religion and worldview. The final section will include a discussion of contemporary cultural and social trends among indigenous peoples of the Arctic, as well as of their recent political struggles for self-determination in the face of climate change and globalization.

Contemporary news flashes about the Arctic typically focus on melting sea ice, drowning polar bears, increased Arctic shipping, and northern oil and gas prospects. Long before the current interest in the geopolitics of the 'New Arctic,' the North captivated the European imagination. Western curiosity about the peoples of the North can be traced back to the ancient Greeks. Still, the scholarly study of the Arctic as an area of shared cultural traits and environmental conditions hardly predates the year 1900. The early twentieth century paradigms of diffusionism and environmental determinism were instrumental in creating the simplistic notion of a unified Arctic or circumpolar culture (e.g., Bogoras, 1929; Hatt, 1914). Detailed ethnographic research conducted since that time has demonstrated that variation is an intrinsic characteristic of Arctic sociocultural systems (some of this research is summarized in Berg, 1973; Graburn and Strong, 1973; Irimoto and Yamada, 1994). Nevertheless, this article approaches the subject by focusing on sociocultural similarities, without denying the existence of considerable differences.

Recent years have seen a tremendous increase in northern circumpolar social science research. In 2004, the *Arctic Human Development Report* (AHDR, 2004) appeared; it provided a first pan-Arctic review and assessment of humanities and social science scholarship. Among other things, the report stated that 'fate control,' 'cultural integrity,' and 'contact with nature' are closely associated with human development and well-being in the Arctic. The *Arctic Social Indicators* project (ASI, 2010) – a follow-up report to AHDR 2004 – made use of these insights and added the above-mentioned domains to the more conventional domains of education, health and material well-being, to come up with a small set of social indicators for the Arctic.

Another important report of these years – endorsed by the Arctic Council (AC) like the others – was the *Arctic Climate Impact Assessment* (ACIA, 2005), which was the first comprehensive regional climate change report that paid attention to the impacts on the residents of that region. Taking into consideration other major projects of the time, such as the *Encyclopedia of the Arctic* (Nuttall, 2005), it is fair to say that the first decade of the twenty-first century was characterized by an unprecedented output of comprehensive and synthesizing Arctic social science and humanities publications.

The Arctic and Its Indigenous Inhabitants

Culturally, the Arctic can be subdivided into a North American and a northern Eurasian part. The North American Arctic is primarily inhabited by speakers of Eskimo–Aleut languages. The old collective ethnonym Eskimo is little used today, and commonly replaced by Inuit and Yupik. Aleut, Yupik, and Inuit societies inhabit the coastal areas of northern North America, stretching from southern Alaska to eastern Greenland. Here the geographical boundary between Arctic and Subarctic coincides more or less with the cultural boundary between Inuit/Yupik/Aleut and Athapaskan and Algonquian groups of North American Indians (*see* Americas, Sociocultural Overviews: North America, Native Americans).

In the northern part of Eurasia, the physical boundary between Arctic and Subarctic does not coincide as neatly with cultural boundaries. In Siberia, the cultural realm of the Arctic extends into the Subarctic ecological zone, and reaches its limits only in the steppes of southern Siberia. Samoyedic Tungusic, and Paleoasiatic languages are spoken by the culturally 'most typical' Siberians. Speakers of Turkic languages inhabit large parts of the eastern Siberian tundra and boreal forest, but their historical and cultural background points to Central Asia. In northern Europe, where the vegetational and climatic zone of the Arctic is narrow, conventionally only the Saami (speakers of Finno-Ugric languages) are considered an indigenous Arctic people. Other peoples, who also inhabit the northern margins of Europe but are organized into large-scale agricultural societies, are not considered in this overview (*see* Europe: Sociocultural Overview).

Indigenous and Colonial Histories

Human habitation of the circumpolar North extends over several thousand years. While the first modern humans expanded into areas up to 60° northern latitude between 45 000 and 20 000 years ago, it was only after the end of the Last Glacial period that the Arctic became fully inhabited by people (Hoffecker, 2005: 8). While the direct presence of European colonial powers in the Arctic is a relatively recent phenomenon, findings of iron and other items that were not

produced locally attest to long-standing connections with trade centers to the South. The territory of the Saami has a history of almost 2000 years of outside intervention, as Vikings pushed north along the western coast of contemporary Norway to extract natural resources and to acquire items of Saami production through trade and tribute. Similarly, European expansion into other parts of the North was fueled by the quest for marketable resources. From the seventeenth century onwards, the rich boreal forests of Siberia and Canada became staging areas for the fur trade. The areas north of the tree line were little affected by fur trapping prior to the twentieth century, but the coastal areas of the Arctic close to the Atlantic and Pacific Oceans became important destinations for the Euro-American whaling industry in the eighteenth and nineteenth centuries.

The early days of colonial rule had little direct administrative impact in many areas of the North. Often it amounted to little more than the purely nominal claim to 'owning' the land, and to sporadic resource extraction. In certain areas, however, the state took a more active role in regulating the lives of the indigenous population: For example, in Greenland a particular form of 'enlightened paternalism' was the guiding principle of Danish rule from the eighteenth century onwards. The second half of the nineteenth century was in this respect far more disruptive than earlier periods: The newly emerging ideology of nationalism brought indigenous peoples from northern Scandinavia to Alaska under increasing pressure to adopt the language and culture of the respective dominant societies.

Domains of Arctic Sociocultural Systems

The following section will provide a discussion of various aspects of 'traditional' Arctic cultures. Using the turn of the twentieth century as the ethnographic present, the material is organized along topical lines.

Ecology and Economy

Characteristic of the Arctic fauna is the relative small number of available species, while the number of individual animals at particular times can be high. Similarly, vegetation north of the tree line is sparse, enjoying only a brief but dramatic growing season. Thus, periods of abundance at a particular locale are followed by periods of shortage, and human groups must schedule their movements accordingly. Due to the wide distribution of permafrost, in combination with climatic and vegetational factors, the practice of agriculture was impossible until recently. Thus, all indigenous Arctic peoples practiced foraging forms of subsistence, such as hunting, fishing, and gathering (*see* Hunting and Gathering Societies: Anthropology).

In the tundra zone, collective hunts of wild reindeer (caribou) during spring and fall migrations constituted extremely important subsistence activities. Along the coasts of the Arctic Ocean the pursuit of sea mammals was life sustaining. Seals formed the staple, and areas visited by migrating whales and walrus had the opportunity to acquire large quantities of meat through one successful hunt. The lower reaches of major rivers provided excellent opportunities for seasonal fishing. The inland areas of boreal forests could generally rely less on one or two major resources, but had to combine hunting (wild reindeer, moose, etc.), fishing, and gathering. The changes brought about by the fur trade triggered dramatic shifts in the seasonal rounds of the peoples inhabiting the Subarctic. The hunt for furbearers, which previously had been of little significance, became the most important economic activity.

The major form of subsistence outside of hunting/gathering/fishing is reindeer herding, a form of pastoralism (*see* Pastoralism in Anthropology). Reindeer domestication is found in northern Eurasia, from northern Scandinavia to the Bering Strait, but did not penetrate into northern North America until the late nineteenth century. Among the various local forms of reindeer herding, two major types emerge. Small herds of domesticated reindeer are found throughout the boreal forest regions of Siberia; their primary use is for transportation during hunting. Large-scale reindeer herding of the tundra, on the other hand, is geared toward the maximization of animal numbers, and provides the group with meat and other reindeer products. The only pan-Arctic domesticated animal is the dog, which is used for transportation (and sometimes as a sacrificial animal).

Most economic production was geared toward household and community consumption. Sharing of resources within these limits was a consistent feature of Arctic and Subarctic societies. Exchange relations with other communities were often facilitated through ritual partnerships, which extended the limits of reciprocity. With the advent of colonialism, production for outside markets commenced: furs, meat of domesticated reindeer, and other products were individually appropriated; they fueled the emergence of economic stratification.

In recent years, many parts of the Arctic have experienced dramatic environmental change, be it climate induced or not (e.g., Keskitalo, 2008). Indigenous residents of the North, who have a long track record of monitoring environmental dynamics, provided detailed observations of these changes (see, e.g., Krupnik and Jolly, 2002). The impact of climate change is not limited to the environment. Traditional ecological knowledge and the social prestige it carries are being eroded by abrupt changes, which prevent accurate forecasts. In addition, modernization and globalization have impacted all so-called 'traditional' economic activities in the North, resulting in 'mixed economies' combining subsistence and cash elements. As has been demonstrated with regard to Aleut commercial fishing (Reedy-Maschner, 2010), contemporary indigenous identities require both economic success and traditional values.

Social and Political Organization

It has long been suggested that Arctic societies are characterized by a bilateral type of social organization (Gjessing, 1960). Traditional Saami societies, the Paleoasiatic groups of northeastern Siberia, as well as the majority of Inuit and Yupik societies clearly fit this pattern. The societies inhabiting the western, central, and eastern parts of Arctic Siberia, however, display patrilineal types of organization. Given the fact that

vectors of cultural influence in Siberia run generally from south to north, it is possible to suggest that unilineal social organization among those groups was stimulated by southern (Central Asian) influences. The unilineal tendencies of certain Yupik and Aleut societies are less easy to comprehend. There are indications of patrilineal 'clans,' sometimes with endogamous tendencies (Petrivelli, 2004); however, the basic bilateral framework of Eskimo–Aleut societies (privileging horizontal links over lineal ties) is also present in these cases.

It is noticeable that none of the Arctic or Subarctic societies of Eurasia show any traces of matrilineal organization. In Subarctic North America, on the other hand, the majority of northern Athapaskans (including the linguistically related Eyak and Tlingit) are textbook examples of descent reckoned in the female line. Generally speaking, the Subarctic forests are dominated by unilineal kinship systems. However, it is unclear whether there is a causal relationship between unilineality and Subarctic lifeways and between bilaterality and tundra lifestyles. While bilateral systems are more flexible and seem more appropriate for small-scale groups scattered over large territories than more rigid unilineal systems, population densities in the boreal forests were hardly larger than in the tundra. On the contrary, certain Arctic coastal communities (e.g., near the Bering Strait) sustained quasi-sedentary settlements of several hundred inhabitants; other than along the mouths of salmon-rich rivers, no comparable population concentrations are known from the aboriginal Subarctic.

Parallel to the fate of kinship studies elsewhere, relatedness as a topic of arctic investigations saw its heydays in the 1960s and 1970s (see, e.g., Burch, 1975; Guemple, 1972; Pehrson, 1964). After a 20-year period of little attention to kinship in the north, the topic has returned albeit with a different set of foci. On the one hand, carefully crafted ethnographic accounts of kinship as lived social relations help us understand the meanings of relatedness in particular Arctic contexts and situations (e.g., Bodenhorn, 2000; Nuttall, 2000). On the other hand, the role of social relations and kinship for economic organization, the sharing of resources, and for the constitution of property relations has become more prominent in recent Arctic studies (see, e.g., Magdanz et al., 2002; Petersen, 2003; Ventsel, 2005).

Throughout the circumpolar North, political organization was local-group oriented and did not entail hierarchies based on hereditary status. Leadership continues to be situational: It is directed toward the solution of group problems, and the decision to comply is voluntary. In addition to seniority, individual achievements are most relevant in gaining leadership positions. The major exception is the case of the Sakha (or Yakut as they were known previously), whose political organization has been characterized as a chiefdom (Graburn and Strong, 1973). For the known cases of ranking in the southern parts of Alaska (e.g., Aleut, Alutiiq), influence from the northern northwest coast of North America (especially from the Tlingit) can be conjectured (Schweitzer, 2003).

Men have often been the only political actors visible to outside observers. Although it is true that many Siberian societies with patrilineal descent have pronounced male-centered ideologies, not all Arctic societies were dominated by 'man, the hunter.' For example, Inuit males, who seemingly provided the large majority of food resources, were entirely dependent on women to process the meat and skin of the slaughtered animals, to make them into usable food and clothing. Thus, the roles of men and women were strongly complementary and did not sustain rigid gender hierarchies.

Religion and Worldview

Shamans and shamanism are probably the most evocative symbols of circumpolar religion and worldview (*see* Shamanism). There is no doubt that – until recently – most Arctic communities had religious functionaries who were able to communicate with and to 'master' spirits. These 'shamans' were engaged in healing and other activities aimed at improving communal and individual well-being. In the small-scale societies under consideration here, these functionaries held extremely important social positions, which sometimes led to an abuse of power. However, the notion of 'shamanism' can easily be misconstrued as a unified system of beliefs, which it never was in the Arctic. Instead, in addition to a limited number of common elements, circumpolar shamanisms show profound differences in the belief systems with which they are associated. Especially in northern Eurasia, elements of worldviews associated with highly organized religions (such as Buddhism or Christianity) found their way into localized forms of shamanism long before the direct impacts of colonialism.

Animism – the belief that all natural phenomena, including human beings, animals, and plants, but also rocks, lakes, mountains, weather, and so on, share one vital quality – the soul or spirit that energizes them – is at the core of most Arctic belief systems. This means that humans are not the only ones capable of independent action; an innocuous-looking pond, for example, is just as capable of rising up to kill an unsuspecting person as is a human enemy. Another fundamental principle of Arctic religious life is the concept of humans being endowed with multiple souls. The notion that at least one soul must be 'free' to leave the human body is basic to the shaman's ability to communicate with the spirits.

Since the killing and consumption of animals provides the basic sustenance of circumpolar communities, ritual care taking of animal souls is of utmost importance. Throughout the North, rituals in which animal souls are 'returned' to their spirit masters are widespread, thus ensuring the spiritual cycle of life. While most prey animals receive some form of ritual attention, there is significant variation in the elaboration of these ceremonies. One animal particularly revered throughout the North is the bear (both brown and black), as has been demonstrated by Hallowell (1926) in his classic comparative study of 'bear ceremonialism.' A recent phenomenological study of the spiritual dangers of hunting among the Siberian Yukaghirs was provided by Willerslev (2007).

The ontologies and cosmologies of the circumpolar north are not unique. Many elements of animistic and shamanic worldviews are widespread among hunter-gatherers anywhere. Similarities among the ontologies of American Indian and Siberian peoples might also have historical foundations, since the peopling of the Americas is thought to have happened through northeastern Asia. Recently, a volume devoted to exploring the similarities and differences between notions of nonhuman personhood in Siberia and Amazonia has

conceptually and geographically extended the notion of Arctic animism (Brightman et al., 2012).

By the twentieth century, hardly any Arctic community had not yet felt the impact of Christian missionary activity. However, there is considerable variation as to when these activities commenced: Christianity reached the Arctic areas of Europe almost 1000 years ago, while the indigenous inhabitants of the Chukchi Peninsula (Russia) had little first-hand experience of Christianity before the 1990s. Generally speaking, the eighteenth and nineteenth centuries mark the major periods of religious conversion in the Arctic. Although no other major world religion has significantly impacted the North, the spectrum of Christian denominations represented in the Arctic is considerable. There is also considerable variation in how 'nativized' the individual churches have become. A good example for the latter, the indigenization of Christianity, are the developments in the southern parts of Alaska after the sale of Russian America to the United States in 1867. These regions – inhabited primarily by Aleut, Alutiiq, Eyak, and Tlingit people, as well as by some Denaina and Yupik groups – came under Russian cultural and religious influence in the eighteenth and nineteenth centuries. While this initial spread of Russian Orthodox Christianity is not different from colonial processes elsewhere on the globe, the persistence of the faith after the end of Russia's colonial rule deserves attention and explanation. Such explanations include references to the specifics of the Orthodox religion (e.g., Mousalimas, 1995), to analogies between indigenous and Russian religious concepts (e.g., Csoba DeHass, 2009), as well as to the identity politics of the early US period of Alaska (e.g., Kan, 1999).

The late twentieth and early twenty-first centuries have experienced renewed missionary activities by 'new' churches throughout the Arctic. A particular focus of missionary activity has been the Russian Arctic, which has been viewed by outside (evangelical) churches as a kind of religious *terra nullius* after 70 years of state atheism.

Contemporary Developments

Throughout the circumpolar North, World War II triggered developments that made the once-distant Arctic frontiers into strategically important areas. The resulting infrastructural and demographic developments altered the social fabric of the North and put an end to official policies of isolationism. The first two decades after 1945 were generally characterized by state policies geared toward 'modernization' and assimilation. It is frightening how similar state policies from Siberia to Greenland were: Native people were relocated from ancient villages to faceless new towns, a new emphasis on 'productivity' favored newly introduced economic activities over traditional subsistence pursuits, and educational systems were reoriented toward nonnative knowledge and skills. It may seem ironic that the very same policies provided the educational infrastructure for those native elites who would challenge the political and cultural hegemony of the colonial powers in the years and decades to come.

Between the 1960s and the 1980s, radical political change affected most parts of the circumpolar North. With the exception of the Soviet North, the general tendency was to repeal colonial status and chart a course toward self-determination. In many cases, opposition to large-scale development projects served as a rallying point for newly developing indigenous movements. For example, the conflict around the construction of the Alta hydroelectric dam in Norway in the late 1970s brought international attention to indigenous causes, and marks a sea change in the political history of the Saami. In Alaska, it was the discovery of oil in 1968 that put the long-neglected topic of native title to land on the agenda. The resulting 'Alaska Native Claims Settlement Act' (1971), which awarded title to 12% of Alaska's land, and cash compensation to newly created native corporations, was then considered a spectacular success.

One of the most impressive results of the era was the 1979 passing of the 'Home Rule Act' in Greenland, which provided limited sovereignty within Denmark (control over most public affairs except defense and foreign relations). In 2009, Greenlandic 'self-rule' was established, the next step toward independence from Denmark. Between 1973 and 1993, Finland, Norway, and Sweden installed so-called Saami parliaments, which – although only advisory – provide Europe's northernmost indigenous peoples with powerful symbols of sovereignty. The most recent change on Canada's political map was the creation of Nunavut in 1999, the first and only Canadian territory in which Inuit make up the majority population.

Developments in the Soviet North followed a different pace. The first 'ethnic' administrative units were formed in Siberia in the 1920s, when such events would have been unthinkable in most other countries, but the political conditions of the subsequent decades reduced notions of 'national autonomy' to mere propaganda instruments. Thus, the reforms of the late 1980s, which led eventually to the demise of the Soviet Union, gave hope for advances in the realm of native rights. Although many changes were undoubtedly positive, the social and economic situation of most native communities in the Russian North deteriorated throughout the 1990s. Many Siberian natives have entered the twenty-first century with nostalgic memories of the Soviet period.

Cooperation among Arctic nations improved after the end of the Cold War, which resulted in the establishment of the AC in 1996 (its predecessor – the Arctic Environmental Protection Strategy – had been founded in 1991). The AC has eight Arctic member states – Canada, Denmark (including Greenland and the Faeroes), Finland, Iceland, Norway, Russia, Sweden, and the USA – and includes so-called 'Permanent Participants,' major indigenous organizations from these countries. It is notable that many of these indigenous organizations are transnational (e.g., the Saami Council or the Inuit Circumpolar Council), that is they represent people who ended up in different nation states as a result of colonial border policies.

The fact that most indigenous Arctic communities have come a long way since the days of colonial rule and outright discrimination should not blind us to persistent problems. Indeed, most communities face a plethora of cultural and social ills, which are enhanced by precarious economic and ecological conditions (see Smith and McCarter, 1997; AHDR, 2004). While many of these problems can be attributed directly to the impact of colonization, the option of isolation from global forces has long since disappeared (if it ever existed). Contemporary Arctic indigenous peoples have

understood that the challenge is not to choose between 'Western' modernity and 'unchanging tradition,' but to find a livable combination of the two. Given the political sophistication of local communities, to work in the North has become a tremendously rewarding learning experience for anthropologists and other social scientists. No longer content with being mere objects of study but, at the same time, realizing the potential benefits of social science, Arctic communities are engaged in an ongoing process of defining collaborative and mutually beneficial research.

Climate change and the wealth of untapped nonrenewable resources in the Arctic make the circumpolar North a region of heightened geopolitical interest. Speculations about the shipping consequences of diminished ice in the Arctic Ocean abound (see, e.g., Anderson, 2009; Smith, 2010). Despite significant increases in Arctic shipping in recent years, future marine traffic in the Arctic Ocean is not just a function of sea ice retreat but of economic demand as well (AMSA, 2009). Awareness of the potential and realized impacts of climate differs significantly in various regions of the Arctic. While local (Inuit) communities in Alaska and Canada have been very engaged in climate change discussions (Marino and Schweitzer, 2009), some communities in the Russian only recently became familiar with the notion of global climate change (Crate, 2008). Drastic consequences in some areas, including coastal erosion necessitating community relocation (Marino, 2012), are counteracted by local perceptions that there are more important things to worry about (unemployment, language loss, high suicide rates, etc.) elsewhere. Likewise, the prospect of increased energy production is met with opposition (see, e.g., Chapman, 2013), as well as with support on the local level. A particular example of the latter is Greenland, where oil exploration is frantic and the parliament recently (October 2013) revoked a law prohibiting uranium mining. This seems to be the price of moving toward the "world's first independent Inuit state" (Nuttall, 2008). While media attention remains fixed on energy riches and territorial claims by nation states, sociocultural processes will decide the viability and future of Arctic communities.

Abstract

Area studies have been one field in American higher education where an in-depth understanding of languages and cultures of other societies has been nurtured. Its institutional development since World War II was the product of financial pressures in funding from the government and foundations. Its intellectual development was the product of changing views of language, discourse, and culture that came to be known as the 'linguistic turn' in the humanities and social sciences. The linguistic turn provided intellectual resources for transforming area studies as it reacted to feminism, ethnic studies, cultural studies, and globalization. The challenge of globalization has revealed some inadequacies in area and cultural studies' uses of a linguistically based concept of culture that relegated culture to shared local differences in the face of macroprocesses of economic globalization. An alternative is to link culture with processes of circulation. In the social sciences and humanities, both the objects of study and their investigators are increasingly in motion; coordinating this 'double circulation' of communities of research and what they study is a central challenge for contemporary area and cultural studies.

Historical Background of Culture and Area Studies

In the twenty-first century, 'area studies' finds itself at familiar crossroads between funding pressures and new intellectual issues. The development of area studies has always relied upon a mix of foundation and federal support. In the early part of the twentieth century, the establishment of the great philanthropic institutions such as the Carnegie Foundation for the Advancement of Teaching (1905), the Rockefeller Foundation (1913), and then the Ford Foundation (1936) provided the initial financial base for supporting research and teaching about other parts of the world, often as an adjunct to the foundations' own activities abroad. Particularly important was the Rockefeller Foundation, whose experiences in China led to its establishment of a humanities program that focused on modern languages and area studies, including the co-funding of an East Asian studies program with the Carnegie Foundation and the American Council of Learned Societies. These activities paralleled the growing public interest in China and Japan; the first area studies organization was the Far Eastern Association (now the Association for Asian Studies), founded in 1943.

World War II brought government support for area studies for explicitly strategic and intelligence gathering purposes. The Far Eastern Association was created under the specter of World War II, and the prospects of a communist China. The containment of communism required understanding the enemy, and it was in this light that the centers of Russian studies at Columbia and Harvard were established with a mix of government (including 'laundered' CIA funding) and foundation support (Cummings, 1997). The Ford Foundation soon became the major private support for area studies. From 1951 to 1966 its International Training and Research Program granted US$270 million to US universities and other institutions, to build research and training programs in area studies. In addition, from 1950 to 1996, it also provided US $87 million to the Social Science Research Council (SSRC) and the American Council for Learned Societies (ACLS) for joint area studies programs.

The key event that changed the public and government perception of area studies was the Soviet launch of the unmanned satellite Sputnik in 1957. The United States was immediately seen as having fallen behind the Soviet Union at every level of education, and by autumn 1958 Congress was set to pass the National Defense Education Act (NDEA). Under Title VI of this act, funds were set aside 'to teach modern foreign languages if such instruction is not readily available'; in addition to language instruction, the government would provide half of the cost of 'National Resource Centers' devoted to the study of specific languages and areas. From an initial annual appropriation of US$500 000, Title VI would grow to US $14 million in 1966. Despite the failure of Congress in 1966 to pass an International Education Act that would have provided additional support for area studies, Title VI and Fulbright-Hays funding continued to support area research and training, including academic infrastructure and library resources. By 1999, there were 119 Title VI centers divided across 11 areas of the world, forming the backbone for area studies.

By the 1990s, 'area studies' was in crisis. Foundation funding had leveled off, enrollments were declining, and the end of the Cold War eliminated one motivation that played so important a role in federal funding: containing communism. At the same time, the intellectual configurations that nurtured area studies were changing. In the early 1990s, the fall of the Soviet Union and a newly emancipated Eastern Europe revitalized interest in civil society and even international civil society, but the initial optimism soon faded with the resurgence of embittered nationalisms. Further, democratization and economic reforms enhanced the status in policy circles of economics and political scientists who wielded more universal models (sometimes criticized as 'one-size-fits-all'), usually based on quantitative analyses of large data sets rather than institutional analyses grounded in intimate knowledge of local histories, languages, and cultures. This approach, embracing

universal theories over those featuring historical and local particularities, challenged the very legitimacy of area studies in the 1990s. (Problems and even failures of democratization and market building came to haunt these more generalized theories and brought back area studies, but only by the end of the 1990s.) Finally, another term began to dominate discussions of area studies: globalization. The challenge of globalization was soon reflected in the proposed reorganization in 1996 of the joint ACLS and SSRC international program that funded much area research and new SSRC policies reflecting this new stress: "Now free from the bipolar perspective of the Cold War and increasingly aware of the multiple migrations and intersections of people, ideas, institution, technologies and commodities, scholars are confronting the inadequacy of conventional notions of world 'areas' as bounded systems of social relations and cultural categories" (Prewitt, 1996, p. 1).

Almost at the same time, the Ford Foundation initiated its 'Crossing Borders: Revitalizing Area Studies' initiative, in which it described area studies as being "at a significant and somewhat tumultuous turning point in its history as it attempts to respond to and illuminate dramatic changes in the world in recent decades and to understand complex relationships between the 'local' and the 'global'." The program would provide US$25 million dollars over a 6-year period in a major effort to respond to the changing conditions that area studies found itself in as it approached the new millennium. By reaching out beyond established area research centers to include colleges and smaller universities, the pool of over 200 proposals provided a snapshot of what were the leading edges of area and international studies in the United States, as they confronted an age of globalization. The initial wave of project proposals took various approaches to rethinking area studies: for example, examining the geographies of diaspora communities, challenging American exceptionalism, exploring legacies of authoritarianism, studying social movements, and alternative modernities.

The intellectual motivation behind many of the proposals was rethinking the very notion of culture and its ties to explicitly national frameworks, as revealed by such new topics as diaspora, ethnicity, and transnational phenomena. These interests contrasted sharply with those in international relations. There were no proposals that dealt with the two themes of civilizational perspectives on culture and globalization as economic development, which were popular in political science at the time (driven in part by the work of Samuel Huntington). Just as area and cultural studies began to 'deconstruct' notions of shared, national cultures, international relations, and development economics combined Max Weber's Protestant Ethic thesis with a comparative civilizational framework from anthropologists such as Robert Redfield, and made civilization-based cultural differences the causal forces behind development (in the West) and underdevelopment (everywhere else) – reflecting the previous (and later defunct) approach to culture and development (or underdevelopment) of the modernization theory of 1950s and 1960s.

The origins of these different approaches to globalization lie in the historical development of the term 'culture.' One important input into area studies has always been the study of languages, especially those of cultures that had their own written histories and literature. These language-based approaches focused on the historical examination of texts, and required both philological and hermeneutic methodologies taken primarily from the humanities; the result was a close tie both in theory and practice between notions of language and those of culture. These concerns often clashed with social sciences-based interests in contemporary societies that focused on strategic issues and economic development, in which language played basically a utilitarian role and was never the source of theoretical insight. An uneasy truce emerged in which area departments were placed in the humanities, while area centers were interdisciplinary and more social science oriented. History departments often acted as a bridge, since they could be located either in humanities or in social science divisions.

One result is that department-based language and civilization introductions to world cultures have often been part of the undergraduate curriculum in many colleges and universities as a part of 'general education.' With the support of federal (NDEA Title VI) and foundation funding, area programs, such as those at Columbia, Chicago, Berkeley, and Harvard universities, were typically built around a large library collection, and tried to create 'vertical' depth in language instruction, history, and literary studies. The area committees of ACLS and SSRC were staffed by area experts specializing in particular parts of the world (Eastern Europe, Southeast Asia, East Asia, etc.) and funded research on these regions. The emphasis was not on international relations issues, but more area-specific work that required in-depth language, culture, and historical training. Area research, thus, tended to draw theoretical and methodological frameworks from the various disciplines they were historically connected to; theoretical advances made first in the disciplines were then applied to area research. The distinctiveness and autonomy of area studies lay not in its theoretical advances, but in language teaching and the translation and preservation of specialized texts.

On the other hand, international relations programs, especially those affiliated with professional schools such as Woodrow Wilson at Princeton, SAIS at Johns Hopkins, the Kennedy School at Harvard, and Fletcher at Tufts, focus on the economics and politics of nation-states. Professional schools usually exist independently of the intellectual agenda of the university, especially the undergraduate curriculum, and, therefore, have had little influence on the debates about general education. However, their impact on undergraduate curriculum has been accelerating, as many universities have made 'internationalizing' their institutions a top priority for both research and teaching; further, such programs tend to have a more 'practical' aura to them (much as business schools do), which has an increasing appeal to students and their parents as higher education has become more expensive and labor markets have become more competitive. International studies majors are proliferating, and often require some mix of economics and area-specific courses, leading some institutions to see international studies as a way to catalyze multidisciplinary work.

New Approaches to Cultural Studies

The close links between traditional area studies and its place within the humanities explains the influence of what has been

termed the 'linguistic turn,' in which problems of meaning, interpretation, and discourse became central to much of the humanities and social sciences. The linguistic turn was triggered by the development of structuralism after World War II. In 1969, Claude Levi-Strauss published *The Elementary Structures of Kinship*, which applied the structural linguistics of Ferdinand de Saussure and the Prague School to the analysis of kinship and exchange relationships. The result was what might be called a 'paradigm' shift that would have a profound influence on French humanities and social sciences, influencing several generations of thinkers that included Roland Barthes, Michel Foucault, Jacques Lacan, Louis Althusser, Jacques Derrida, and Pierre Bourdieu. It would serve as a lightning rod for the development of feminist, ethnic, and cultural studies in the 1970s and 1980s.

Structuralism arrived in the United States in the mid-1960s, and in 1966, there was a famous colloquium at Johns Hopkins on 'The Languages of Criticism and the Sciences of Man,' in which Derrida, Barthes, Lacan, Gerard Genette, Jean-Pierre Vernant, Lucien Goldmann, Tzvetan Todorov, and Nicholas Ruwet participated. What was impressive was not only the caliber of thought, but its range, including literary criticism, psychoanalysis, history, philosophy, semiotics, and linguistics. Although united underneath a structuralist banner, the conference also introduced poststructuralist thought to US audiences. Poststructuralism would make its initial beach-head at Johns Hopkin's University and would soon conquer comparative literature departments such as Cornell and Yale where the so-called 'gang of four' of Paul DeMan, James Miller, Geoffrey Hartmann, and Harold Bloom would consolidate what came to be known as 'deconstructionism.'

While structuralism had little direct effect on area studies, the focus on language and meaning would have a huge impact across many disciplines. By the late 1960s, the triumvirate of Noam Chomsky, Jean Piaget, and Levi-Strauss promised to uncover the 'deep structures' of the human mind and society. Analytic philosophy focused on the 'ordinary language philosophy' of John Austin, Ludwig Wittgenstein, and the more formalist work of Quine, Kripke, and Davidson. Besides French-based structuralism and poststructuralism, the more German hermeneutic tradition represented by Hans-Georg Gadamer combined with the Weberian tradition of *verstehen* analysis to influence thinkers as diverse as Clifford Geertz and Jurgen Habermas. The result was that at some of the leading 'area studies' research universities, such as the universities of Chicago and Columbia, language and discourse became models for cultural analysis. The rise of symbolic anthropology at the University of Chicago quickly set off an 'interpretive turn' associated with such figures as Marshall Sahlins, Victor Turner, David Schneider, Stanley Tambiah, and Clifford Geertz; all except Sahlins would move elsewhere, thereby transforming the field's core from social to cultural anthropology.

At Columbia, the presence of Edward Said and Gayatri Spivak would pave the way for what would become known as postcolonial studies. At Berkeley, Stephen Greenblatt would develop what became known as the 'new historicism,' which was itself heavily influenced by the mix of history and anthropology developed by Geertz. The interest in meaning and discourse would quickly spread from anthropology and literary studies into area studies as part of what became more generally known as the 'linguistic turn,' a term coined by the philosopher Richard Rorty (1967) and applied first to analytic philosophy. The term was quickly applied to all language-based inquiries, as indicated by Rorty's own work on deconstructionism and Derrida. At the same time, there was a dramatic increase in the number of foreign graduate students, especially from South Asia, East Asia, and Latin America whose interests in contemporary cultural developments in their home countries contributed to the growing interest in popular culture triggered by cultural studies. The relaxation of immigration restrictions in the 1960s also increased their presence among the US faculty.

The introduction of these language and discourse themes in the late 1960s and early 1970s would intersect with the development of new social movements inspired by the civil rights movement and the events of 1968. The rise of feminism and ethnic studies (especially on the West Coast where there were degree-granting programs in ethnic studies) catalyzed research into alternative, nonmainstream histories. Poststructuralist formulations of subjectivity and identity, along with neo-Marxist analyses of culture provided not only new theoretical frameworks, but also new areas of study that challenged traditional area studies. British cultural studies introduced a theoretically sophisticated discussion of the mass media and popular culture, including Althusser's reworking of Marx and Lacanian film analysis. Cultural studies entered the United States through communications programs, most notably at the University of Illinois at Champaign–Urbana. Because of its origins in England (the so-called Birmingham school) and its location in communications studies in the United States, it initially had no impact on area studies or anthropology. However, as it became increasingly apparent (most dramatically by the events of 1989) that popular culture and the mass media were playing a crucial role in the development of societies that were the traditional object of area studies, its influence quickly spread to the point where anthropologists began complaining about how cultural studies were invading their domain and control of the concept of culture.

Even approaches that were not structuralist or poststructuralist contributed to the linguistic turn. The Frankfurt School critiques of mass culture were updated by Jurgen Habermas' work on the public sphere (Habermas, 1989; Calhoun, 1992) and then his explicitly linguistically based theory of communicative action (1984, 1987) and his critiques of poststructuralism. His ideas would introduce a distinctly communications-oriented dimension to the civil society discourses that became popular after the downfall of communism. Benedict Anderson (1983) would draw upon Walter Benjamin's work for his provocative theory of the communicative origins of nationalism, while Charles Taylor's hermeneutic explorations into the origins of Western concepts of the self (1989) invited comparative work.

The development of these trends paralleled the expansion of area, ethnic, and cultural studies in the 1970s and 1980s. Yet, if the events of 1968 could be said to roughly herald in the linguistic turn in the United States, the events of 1989 would prove to be the beginning of its demise. The downfall of communism began the undoing of not only Marxist discourses, but also the relevance of the more politicized domestic versions

of multiculturalism and identity politics for global comparisons. The civil society discourse that seemed to hold such promise at the end of the 1980s would quickly unravel in the 1990s, as the uneven development of Eastern Europe and Russia, the clampdowns in China, and the rise of new nationalisms and fundamentalisms questioned the viability of the civil society concept in an age of globalization.

Whereas in the 1970s and 1980s, theory was very much 'at the cutting edge' of the linguistic turn, by the mid-1990s, 'globalization' had replaced it, not so much as a theoretical category, but rather as an empirical challenge to the standard disciplines and area studies. The transition from the linguistic turn to globalization formed the intellectual backdrop to the Ford Foundation's Crossing Borders Initiative. The over 200 proposals represented the state-of-the-art in area studies, as it attempted to deal with contemporary global transformations. While there was a large variety in theoretical approaches, none emerged as predominant. Instead, most striking was the range of phenomena that the proposals tried to deal with, from opening up ethnic studies and globalizing identity politics, to reconfiguring notions of areas and regions (e.g., thinking of oceans as areas). One lacuna was particularly noticeable and undoubtedly fed into the crisis feeling about area and cultural studies. Despite the calls for interdisciplinarity, there were no proposals that dealt substantively with the relation between economics and culture.

This problem was not unrelated to the linguistic turn in cultural analysis. Despite some innovative works by the literary scholar Mary Poovey (1998) and the philosopher Ian Hacking (1970, 1975), interpretive approaches developed for and applied to literary and historical texts have not been easily transferred to the analysis of mathematical and statistical data. The inability to treat these discourses as cultural phenomena has heightened the split between economic and cultural analyses, just at the moment when historical economics was being eliminated in many economics departments. This gap was exacerbated by the collapse of Marxism, which in the hands of the Frankfurt School and contemporary thinkers such as David Harvey (1982, 1989) and Frederic Jameson (1998), had at least tried to keep the analysis of the relations between culture and capital alive.

Cultural Studies and Globalization

The textual focus also overlooked dynamics of circulatory processes in which texts are embedded and transmitted. Text-oriented approaches often assumed the fixity of the text artifact and such categories as author, reader, audience, and the act of reading itself; even destabilizing moves of deconstructionism presupposed elitist conceptions of reading and re-reading. The linguistic turn's focus on the interpretation of texts, and discourses and the analytic frameworks derived, produced a paradox: the more approaches treated texts or discourses as intrinsic objects of analysis, the more difficult it was to understand the norms of the interpretive communities that made such approaches possible, that is, the context that makes interpretation possible. A focus on texts and discourses per se overlooks how they serve as ways of connecting individuals and groups and how these connections create various kinds of interpretive communities. Yet, if contemporary globalization involves the creation of new forms of connectedness through a globalized market, mass media, and new technologies, then it is not surprising that the linguistic turn has become increasingly anachronistic as it confronts these phenomena.

Globalization presents a unique challenge to area and cultural studies. A focus on language and identity leaves economic processes unanalyzed. If the seeming triumph of capitalism indicates that the leading edge of contemporary changes is the spread of homogenizing economic processes, then analyses that focus on the cultural dimensions of identity formation seem doomed to play catch-up with forces beyond their control. The civilizational approaches developing in international relations invoke cultural values to explain the failure to develop, thereby presupposing that economic success depends on adopting what are basically Western cultural values; a holistic conception of shared culture as civilization-based values provides the diacritics for developmental differences. Given the historical trajectory of area and cultural studies, it seems highly unlikely that they can go back to a conception of culture that they have been abandoning over the last several decades.

Instead, there is a growing realization in area and cultural studies that while globalization has produced many convergences in institutions and practices across societies – market economies, bureaucratic states, parliaments, elections – these differ significantly from society. Unlike the rhetoric of economic development, globalization is not a single process spreading across the world. Instead, it spreads through diffusion, influence, imitation, negative reaction, borrowing, and so on that work across complex circulations of goods, technologies, ideas, images, and forms of collective imagination. At the same time, the velocity, scale, and form of these processes and circulations challenge virtually all existing narratives of culture, place, and identity and the intellectual and academic frameworks used to study them.

The complexity of these global processes suggests that if circulation is to be a useful analytic construct that replaces more traditional notions of shared culture, it must be more than simply the movement of people, ideas, and commodities from one culture to another. Instead, recent work suggests that circulation is a cultural process with its own forms of abstraction, evaluation, and constraints that are created by the interactions between specific types of circulating forms and the interpretive communities built around them; the circulation and interpretation of specific cultural forms creates new ways of connecting individuals and groups that can be the bases for social movements, identity formations, and communities. A much cited example would be Benedict Anderson's claim that novels and newspapers help people imagine forms of connectedness among strangers that are at the heart of the idea of nationalism. However, similar themes run through Habermas' work on the public sphere, the Chartier group on print mediation (Chartier, 1989, 1994; Martin, 1994), and Arjun Appadurai's on global flows and 'scapes' (1996).

The linking of circulation with the construction of different types of imagined and interpretive communities also provides a way of overcoming some of the barriers between cultural and economic approaches to globalization. In much of the

contemporary work on globalization, culture is seen as that which is subjectively shared by a community and is, therefore, local. Economic processes are seen as objective, universal, and global. Often overlooked, however, is the interpretive dimension of economic processes. Global capital flows presuppose the intertranslatability of financial instruments and information technologies while at the same time demanding that 'local' economic activities be translated into cross-culturally comparable statistical categories. The circulation of financial instruments rests upon this work of translation and depends upon an interpretive community of institutions (e.g., exchanges, banks, and clearing houses) that understand and use these forms.

What these phenomena share is an internal connection between circulating forms and the forms of connection and community built around them. Communities are built around the ways they connect individuals and groups. The ways they are connected depend upon the circulation of specific cultural forms that both enable and constrain how they are to be used and interpreted. Whether it is the novels, newspapers, magazines, publishing houses, and coffee houses and salons of Anderson's and Habermas' accounts of nationalism and the public sphere, financial derivatives or junk bonds, or the architecture and codes of the Internet, interpretation and circulation interact to create new forms of collective subjectivity. Instead of simply being the movement of people, ideas, and commodities from one culture to another, circulation is a cultural process with its own forms of abstraction, reification, and constraint. The circulation of a 'community' of forms creates new forms of community with hierarchies of evaluation, contrast, and difference; what might be called a 'culture of circulation.' A culture of circulation would be a 'translocal' form of connectedness that might have the geographical reach of a civilization, but not its fixity or sharedness. It is from these cultures of circulation that new forms of subjectivity and consciousness arise that are the bases for the political cultures of modernity, including the public sphere and nationalism.

Arjun Appadurai (1999) has suggested that research should be thought of as an imagined community that spreads through the global circulations of people and ideas as well as institutions and practices. The peculiarity of area studies is not that it is an interpretive community within the larger cultural circulations that characterize modern research; that would be true of any research community. Instead, its potential as a form of knowledge lies in its self-reflexivity. Its objects of study are cultures of circulation of which it is a part. Both the objects of study and those who study them are increasingly in motion. This 'double circulation' is already creating new communities of research that challenge traditional models of area study by decentering the Euro-American Academy as the main source of innovative research; postcolonial studies may be the welcome harbinger of things to come. These confrontations are not simply producing competing hypotheses that can be tested for their validity, but are rather the indices of new research imaginaries in the making. A self-reflexive area studies, instead of just providing the data to test theories generated in other disciplines, would be at the cutting edge of understanding the conditions for the production of knowledge in an age of globalization.

Abstract

Modern 'political economy' explores relationships among economic and political organizations, institutions, policies, and outcomes. There has never been a consensus on the theories and methods that should structure the exploration of these relationships and the debate over how best to understand these matters has evolved over time. The interpretation offered here simplifies both of these dimensions of difference. It distinguishes two periods of postwar history – the Fordist and Neoliberal eras – based on the dominant paradigm of economic organization prevailing in the rich capitalist democracies of the global North. For each period, the most important theoretical approaches to political economy, the regions of the world to which they were applied, and the social science departments in which they were based are identified. It is argued that, in the second or neoliberal era, political economy analyses can be broadly grouped into those that took a critical stance on existing economic paradigms, institutions, and policies, and those which accepted the core assumptions of neoclassical economics and the neoliberal policies and institutions that this approach to economics has legitimated. The relationship between area and international studies and political economy varies, both by period and, to some degree, by the type of political economy in question.

Modern 'political economy' explores relationships among economic and political organizations (e.g., states, corporations, and unions), institutions (e.g., laws and practices regulating trade and competition), policies (e.g., restrictions on international capital mobility), and outcomes (e.g., rates of economic growth, political regime stability). Political economists differ along several important dimensions, as discussed below. This article offers an overview of the evolution of competing versions of political economy, and their relationship to Area and International Studies, since World War II.

The Fordist Moment

The classical political economists of the late eighteenth and nineteenth centuries – Smith, Ricardo, Malthus, Marx, and J.S. Mill – addressed fundamental questions such as the appropriate economic role of the state, the implications of trade liberalization for the economic fortunes of different economic classes, the ecological constraints on continuous economic growth, and the economic and political contradictions of different modes of production, including capitalism.

In the first quarter-century after World War II, some of these questions remained at the center of debates between modernization theorists (Rostow, 1960) and dependency theorists (Cardoso and Faletto, 1979) who argued about the logics of, and possibilities for, economic and political development in what the Cold War framed as the Third World. Marxist versions of political economy became the new orthodoxy in the Second World, which soon encompassed most of Eastern Europe and much of Asia. In the First World, however, most students of market dynamics within economics departments began to abandon political economy approaches. Prior to World War II, when institutional economics remained the dominant tendency in the economics departments of the United States, this break with the core assumptions and research agendas of political economy had gone furthest in the United Kingdom. However, after the war, British neoclassical microeconomics and Keynesian macroeconomics gained ground rapidly in the United States. In the Cold War context, the dominant theoretical orientations of the US hegemon exerted a powerful gravitational pull on social science in the academies of the First World.

The new mainstream economists had a much narrower intellectual agenda. At the micro level, they drew on the pioneering work of Marshall and Pareto in an effort to demonstrate by formal, mathematical means the superiority of competitive markets as efficient allocators of resources. Arguments for trade liberalization and critiques of most forms of state intervention in market allocation processes were developed in this spirit. At the macro level, in First World economies, the new mainstream drew on Keynes in an effort to theorize how best to employ fiscal and monetary policies to reduce the amplitude of business cycle fluctuations. There were significant tensions between these micro- and macroeconomic agendas; however, they only became salient toward the end of this period.

Most of the new mainstream economists – whether micro or macro in focus – sought quasinatural laws governing market dynamics regardless of time and place. They paid little attention to the political and institutional parameters within which markets existed or to the balance of power among social forces that shaped these parameters. There was an irony here. The divorce between politics and economics in First World academic economics was possible because a new kind of political economy – sometimes called 'Fordism' (Lipietz, 1987) – was developed after World War II. The institutional and political details of Fordist regulation varied from country to country but everywhere it represented a fundamental shift away from wage regulation through competitive labor markets maintained by the repression of worker rights, to form democratic unions and engage in collective bargaining. Fordist

institutions linked national real wage growth to the expansion of national labor productivity through some combination of collective bargaining (e.g., pattern bargaining in the United States) and state regulation (e.g., minimum wages) (Piore and Sabel, 1984). Fordist regulation generated higher rates of economic growth and distributed the gains from that growth more broadly among the workforce than any form of economic regulation before or since (Marglin and Schor, 1990). These successes contributed to the depoliticization of economic policy, which could more easily be seen as an administrative matter to which there were technical answers. This facilitated the shift away from political economy's focus on the reciprocal relationship between political power and economic outcomes.

Non-Marxist versions of political economy remained a significant current within the comparative politics subdiscipline of political science in this period. In the Cold War struggle, a great deal of public research funding was made available to those pursuing such studies (Gendzier, 1985). Area studies encompassed the countries of the Second and Third Worlds, where the influence of Marxist political economic analysis was strong among state elites, academics, and organizations such as unions and cooperatives. Hence, First World academic analysts found it necessary to engage questions of class power, organization, and institutions in studying these countries. To this task most brought Weber and Durkheim, as interpreted and synthesized by Talcott Parsons, under the rubric of modernization theory (Leys, 1996).

Area studies thus helped to preserve political economy when it was marginalized in the economics departments of the First World countries in which it had originated. In turn, political economy offered a coherent basis for distinguishing among different areas. Latin America, for example, made sense as a region to be contrasted with others because most of its states shared a particular kind of political economy. In the nineteenth century, the countries in this region were characterized by primary commodity production for export, and republican regimes that secured their independence from Iberian empires. In the crisis of the 1930s, most of these countries embraced a particular kind of economic development strategy – import-substitution industrialization – that gave rise to parallel economic and political dynamics, including the rise of a significant industrial working class and the formation of corporatist political systems.

There was no parallel symbiosis between political economy and the International Relations (IR) subdiscipline as it existed in US political science in this period. IR was dominated by international security debates between those who supported a *realpolitik* firmly rooted in a narrow account of national self-interest and those who asserted that international cooperation rooted in shared liberal values was a surer guide to national security and world peace. IR paradigms, particularly as they were formalized by Waltz and his followers, took it as axiomatic that states were highly autonomous from the domestic societies in which they were embedded, at least as regards the formation of foreign policy (Waltz, 1959). On this view, the international distribution of state power resources (e.g., concentrated in two rival superpowers versus dispersed more evenly among leading countries organized into alliances), and differences in state elite strategies for realizing their power maximizing objectives were the main explanations for variations in state behavior and resulting international dynamics (Krasner, 1976). States might liberalize trade as part of their grand strategies for enhancing their power relative to their rivals, but there was little reciprocal causality in this model. That is, neither international economic dynamics nor classes defined in economic terms had much impact on state goals or strategies.

Beyond IR as practiced in the United States, International Studies in these years was roughly equivalent to diplomatic history. Greater methodological and theoretical eclecticism created more space for recognizing the significance of domestic factors in international relations. A few approached these matters from standpoints that paid greater attention to the kinds of factors highlighted by political economy. Still, most studies of international diplomacy remained in the realm of 'high politics,' and so had only passing contact with the methods and concerns of political economy.

The Neoliberal Moment

As the Fordist economic order began to disintegrate in the late 1960s, many argued that both the causes of the crisis and the remedies for it lay in changes in the balance of economic and political power among nations, between labor and capital within nations, or both (e.g., Gourevitch, 1986). Economics and economic policy were thus repoliticized as an intense political struggle over how to understand and respond to the crisis of Fordism under way. In this context, rival strands of political economy emerged, each associated with advocates of a different response to the crisis. Critical political economists – a diverse group influenced in varying degrees by Marx, Weber, and Polanyi – were concentrated in political science and sociology departments. This strand of political economy was strongest among area specialists who focused on Latin America, Asia, and Western Europe and among students of peasant rebellion and social revolution. Their diagnoses of the crisis tended to support policies that would reinforce and extend the basic principles of Fordist regulation, or a move beyond capitalism to some form of democratic socialism.

Neoclassical political economists began from the premise that neoclassical accounts of economic dynamics were basically sound, as were capitalist economies. The problem as they saw it was how to develop an equally sound science of political dynamics, a science that would explain why state intervention could seldom improve on market outcomes, even when market failures were acknowledged. Some sought to build a new political science on the 'rational choice' premise that all individuals and organizations are instrumentally rational, self-interested actors (Alt and Shepsle, 1990). Others were less programmatic, turning traditional analytic tools to the service of policy goals deriving from neoclassical economics. The first strategy generated theories of 'rentier' states and 'political failure' paralleling the theory of market failure that justified Fordist regulation on efficiency grounds (Kruger, 1974; Bates, 1988). These analyses, together with neoclassical microeconomic doctrines, provided the intellectual rationale for 'neoliberal' policy prescriptions – that is, redefinition as the primary economic role of the state as the creation and maintenance of competitive markets. The second strategy generated

(among other things) assessments of strategies for implementing structural adjustment policies successfully in democracies where popular opposition to such policies was widespread. The neoclassical strand of political economy was concentrated in economics and political science departments (particularly in the United States).

The neoclassical approach to political economy was very much in tune with the neoliberal response to the crisis of Fordism championed by the United States under Ronald Reagan and the United Kingdom under Margaret Thatcher. The Third World debt crisis soon facilitated the export of neoliberal policies, via conditions imposed on debtor nations in return for assistance in restructuring their loans. In this context, neoclassical political economy became the more prominent of the two approaches, particularly among policy elites and in the United States. However, there were important intellectual innovations within both tendencies. The result was a renaissance of political economy analysis in the neoliberal era, with both the form and the implications of that analysis intensely contested.

World systems theory was an important strand of the critical political economy analysis that emerged in this period (Wallerstein, 1976). While influenced by earlier dependency theories, world systems theory was distinctive in two ways: the degree to which it treated the international economy as a system governed by its own systems-level logic, and the degree to which that logic was seen to determine the development possibilities of the nations whose system functions marked them as peripheral or semi-peripheral. World systems theory took hold primarily in sociology departments, where Marx enjoyed more equal status with that of Durkheim and Weber.

A second strand of critical political economy, with institutional roots in sociology and political science, emerged under the banner of 'bringing the state back in' (Evans et al., 1985). This strand explored the significance of national differences in state characteristics and relations between the state and societal actors, factors that were treated as secondary in most world systems analyses. Within the Third World, critical political economists began to explore the social and political consequences of structural adjustment policies in Africa and Latin America in the wake of the debt crisis (e.g., Bierstecker, 1995). There was also increased interest in the role of 'developmental states' in enabling a small number of countries – concentrated in Asia's Newly Industrializing Countries – to escape the travails of the debt crisis and successfully reorient national economies to an export-driven model of industrialization (e.g., Evans, 1995). Finally, a literature emerged on the export processing zones created in many countries subject to neoliberal restructuring, and on the international supply chains that linked them to First World corporate producers and retailers (Gereffi and Korzeniewicz, 1994).

A strand of neoclassical political economy also focused on the world system. Most important here was the 'hegemonic stability' theory advanced by the self-styled neorealists and their neoliberal interlocutors. These analysts, located within international relations sections of political science departments, mainly in the United States, debated the extent and significance of the decline of US economic hegemony evident by the late 1960s. Hegemonic stability theories asserted that, without disproportionate US economic power, the international monetary system created at Bretton Woods and multilateral trade liberalization under the auspices of GATT (General Agreement on Tariffs and Trade) would not have been possible (Gilpin, 1987). They interpreted the collapse of fixed exchange rates and an alleged shift toward protectionism in the form of 'nontariff barriers,' as evidence that the postwar international economic regimes constructed by the United States were indeed unraveling.

Neoliberals such as Keohane drew on game theory to argue that states *qua* rational actors might choose to support and extend trade liberalization and other aspects of international regulation out of an enlightened sense of self-interest, even in the absence of a hegemon, under certain conditions (Keohane, 1984). Other neoclassical political economists took a different tack, identifying a variety of societal, institutional, and ideological factors that might explain why the US state maintained its trade-liberalizing trajectory in the 1970s and 1980s, despite declining US economic hegemony and rising social costs (e.g., Goldstein, 1993). Among neoclassical political economists focusing on the global South, attention was devoted to explaining the wave of democratization that began in the late 1970s, particularly to possible links between economic liberalization and democratization.

In the 1990s, the end of the Cold War and the acceleration of the economic globalization – by which analysts generally meant increased international trade and capital mobility, and sometimes also neoliberal policies such as privatization and deregulation – shifted the focus of research and the terms of debate. The concepts of the Second and Third Worlds were rendered obsolete; many analysts began dividing the world into the 'global North' (i.e., rich capitalist democracies) and the 'global South' (i.e., all others). An important debate developed concerning whether there was anything sufficiently novel about the international economy of the 1990s to warrant the use of the term globalization (Held et al., 1999). There was also great interest in the causes and consequences of economic globalization. Neoclassical political economists tended to take a positive view of economic globalization and often treated that the process as natural and/or inevitable. Critical political economists typically saw the shift as the product of power politics within and among nations and its negative affects as more substantial (Cox, 1994). There was great interest in whether this new economic order was significantly narrowing state policy autonomy, forcing governments toward a more *laissez-faire* model of economic organization regardless of their political stripe and the preferences of voters (e.g., Rodrik, 1997). There was also interest in the implications of economic globalization for the power of organized labor (e.g., Kitschelt et al., 1999). Finally, there was growing interest in the origins and character of organized resistance to the neoliberal model of globalization, a discussion leavened with the insights of social movement theory (e.g., Castells, 1997), as well as more traditional political economy approaches (Arrighi et al., 1989).

These developments had important implications for the evolution of area and international studies. The resurgence of political economy strongly legitimated international studies' supranational and interdisciplinary character and added another important approach to how such work might be organized. As to area studies, political economy may afford new grounds for drawing area boundaries. For example, since

the passage of the North American Free Trade Agreement (NAFTA) in 1993, Canada and Mexico have become much more integrated with the US economy. For many of the questions of interest to political economists, it now makes sense to treat North America as a region to be studied as a unit. This contrasts with the old area study practice of studying the United States in splendid isolation, Mexico as part of Latin America, and largely ignoring Canada. Similarly, as East European countries have joined the European Union (EU), it remains sensible to frame many political economy questions in terms of a new EU region that straddles what were once regions in the First and Second Worlds. This said, this last statement depends on whether the EU will survive the shocks of the 2008 global economic crisis and the subsequent crisis in the euro. While the Greek crisis raised the specter of the collapse of the euro or its reduction to a 'northern euro' (centered on Germany and northern Europe), the stabilization of the European economy (albeit without hoped-for growth, given continuing austerity measures) reduced the threat that the EU would fall apart (although as of this writing it is unclear whether the United Kingdom will retain its ties with the EU). After the shocks of 2008 threatened EU implosion, Vladimir Putin's takeover of Crimea and sponsored civil war in eastern Ukraine might be the stimulus to bring EU countries closer together. However, the years since 2008 have been a period of geopolitical instability, and at this moment it would be foolish to presume either EU expansion or collapse.

A Brief and Uncertain Postscript: Post-2008 Political Economy

This brief discussion of the EU after the global crisis of 2008 highlights a more general issue of this moment in time: that the crisis might provide a potential moment of transition or retrenchment of models of political economy. The extent to which national economies were interconnected was laid bare once the American housing bubble burst and American financial institutions suddenly faced severe challenges to their very survival. At the same time, the degree of local autonomy was also revealed in how various actors went in different directions vis-à-vis responses to recessions: for example, from more state-centered responses in China and Russia, to austerity policies in the EU, to less austerity-oriented but still market-friendly policies in Barack Obama's United States. Further, the degree to which public policies have reflected interests and ideologies deserves study that at this point in time remains to be done. As Paul Krugman argued repeatedly in his *New York Times* blog, austerity policies have been disastrous, and so the only reason they were adopted and persisted was a combination of particular elite interests and ideologies about the 'normal' way states approach political economy and economic crises. As Piketty (2014) revealed in his rigorous study, inequality has been a defining feature of modern economies, and while there are possible responses to improve equality and reduce risks of future shocks, it is unclear whether political and economic elites will accept these. For example, German politicians and public have been averse to allowing inflation to rise: while this might have a negative short-term impact on Germans themselves, it would benefit the EU, and Germany as well, in the medium to long term. Yet, in German political discourse, inflation is framed in terms of the catastrophic post–World War I economic situation, as well as morality play in which German productivity and frugality would appear to be punished for the sins of other European countries and societies that took on too much debt. As well, American elites for the most part have been willing to pursue austerity measures that ultimately have hindered the American recovery; circumstantial evidence suggests this is not only because of interests but also because relatively more Keynesian measures (such as fiscal stimuli and more equitable distribution of the tax burden) would contradict the hegemonic elite ideology in which the state is the source of economic troubles and the business elite the source of its solutions. Finally, the global economy has come under some scrutiny since 2008. While globalization still appears inevitable, actors from various social movements have asked whether that global order need appear as it does. The rise of the BRIC countries (Brazil, Russia, India, and China) presented a potential competitor to the hegemony of the United States and Europe, and while the 2008 crisis reduced BRIC growth, the idea of a new bipolar world – with power balanced between the United States and the EU on one side, and the BRICs on another – is a distinct possibility, especially as Russian leaders Vladimir Putin and Dmitrii Medvedev more than once proposed that BRIC countries plus South Africa form their own form of economic alliance to counterbalance 'the West.'

The possible rearrangement of global relations and positions, and the problematic and contentious (and sometimes seemingly puzzling) nature of public policies in response to the 2008 crisis should force us to revisit what we mean by 'political economy' and how to analyze it. If the story since 2008 is anything to go by, Karl Marx and Max Weber would be happy, as their stresses on the centrality of elites, states, and especially power and contention to any analysis seem borne out by recent events.

Area and International Studies: Stakeholders

Gilbert W Merkx, Center for International Studies, Duke University, Durham, NC, USA

Abstract

In most nations, the stakeholders in area and international studies (A&IS) are government agencies. However, in the United States, A&IS stakeholders are found in education and the private sector as well as in government, resulting in a high level of organizational development, complexity, and productivity. A&IS represent a crossing point between academic disciplines, research and policy institutions, numerous ethnic foreign-language communities, various international exchange organizations, foreign and domestic corporate interests, national security agencies, and issue-oriented oppositional movements. As a result, the A&IS enterprise is contested by shifting coalitions defined by such factors as professional self-interest, intellectual paradigms, national security threats, and ideological agendas.

The various A&IS stakeholder communities can be divided into three major categories: the producers of knowledge (individuals and institutions, as well as the associations that represent them), the consumers of knowledge (in the form of information or in the form of A&IS-trained personnel), and the investors (in both production and consumption).

The Producers of A&IS

The institutional locus of A&IS varies across nations. This locus is a key determinant of the complexity of the stakeholder community. In many countries, including France, the former Soviet Union, and China, A&IS research and training is located in national academies, or government-funded think tanks (Lambert, 1990: pp. 712–732). These are self-contained nonuniversity institutions whose staff and students are devoted to language training, empirical research, and policy analysis. A variant, most notably in Great Britain, is the free-standing research institute devoted to philology and historical studies of a foreign civilization. Such self-contained institutes are separate, and often distant, from institutions of higher education in their countries. As a consequence, A&IS expertise in these countries is generally not conducted with reference to the standards of the academic disciplines, but represents a nondisciplinary or multidisciplinary tradition that serves as its own point of reference. The stakeholders are basically limited to the area specialists in the national academies and their client government agencies with foreign diplomatic, economic, military, or national security concerns.

In contrast, A&IS in the United States are found primarily in institutions of higher education, particularly in the research universities. The standard organizational model consists of a coordinating center or institute that offers the less commonly taught languages, while the more commonly taught languages and relevant courses in the various academic fields are offered by the disciplinary departments. The A&IS faculty are employed by these departments and judged by them for tenure and promotion. As a result, research and teaching in A&IS are judged primarily by disciplinary standards. Faculty in A&IS programs have primary appointments in disciplinary departments, teach courses in those departments, and conduct research in those disciplines. Thus, while the A&IS programs are interdisciplinary inasmuch as they list faculty and courses from different disciplines, A&IS teaching and research are almost exclusively disciplinary in nature. A&IS graduate degrees, especially PhDs, are therefore normally conferred in a discipline. Department of Education data for all graduate degrees produced by federally funded comprehensive A&IS centers in the 1991–94 period show that 91.5% received disciplinary or professional degrees, while only 8.5% received area studies degrees, and these were largely at the MA level (Schneider, 1995a: p. 9, Table C). Even those programs that award a graduate degree in study of a foreign area do so through a curriculum based on disciplinary courses offered by departments, usually with a disciplinary major.

Because of this integral relationship to higher education, A&IS is far more developed in the United States than in other countries. In the year 2013, federal funding through Title VI of the HEA supported 127 comprehensive (graduate and undergraduate) A&IS centers at colleges and universities, as well as smaller numbers of undergraduate international studies programs, undergraduate international business programs, graduate centers for international business education and research, foreign-language resource centers, and overseas research centers. A&IS programs that do not receive federal funding are far more numerous, at least four times the number receiving aid. The total number of formally organized A&IS programs in the USA is in excess of 500.

The A&IS stakeholders in the U.S. system are far more varied than in countries with the national academy model. The faculty members involved in the academic programs are usually members of disciplinary associations (such as the American Historical Association), and members of A&IS professional associations (such as the Latin American Studies Association and the International Studies Association), which means that these associations also are stakeholders.

The membership of the A&IS professional associations are a guide to the size of the knowledge producer population. Although only about two-thirds of the area studies association's membership are faculty, not all foreign-area studies faculty belong to these associations. Past studies have therefore estimated that total membership in the area studies association provide a good approximation of faculty employment in foreign-area studies (Lambert et al., 1984: p. 13). The total membership of the five major area studies associations, which cover Africa, Asia, Latin America, the Middle East, and the

former Soviet Union and Eastern Europe, was approximately 16 000 in 1990 (NCASA, 1991). This compares with a 1979 membership in all area studies associations of about 18 000. If the 1990 memberships of the smaller area studies associations such as Brazilian, Canadian, European, and Caribbean studies are added to those of the five major associations, the total remains approximately 18 000, about the same as in 1979 (Barber and Ilchman, 1977: p. 15). These numbers have been relatively constant in the two decades since then. Membership in the International Studies Association adds another 3000 persons, for a combined total of 21 000. Another faculty stakeholder group is foreign-language and literature teachers, for whom two sources of information exist, membership in professional organizations, and surveys of the National Center for Education Statistics of the U.S. Department of Education. Using these two sources, a recent study estimated a total 36 000 postsecondary language and literature faculty (Merkx, 2000: pp. 93–100). Added to the previous groups, the estimated total of faculty stakeholders is about 47 000 persons.

Campus units that support A&IS, such as the library and the language departments, have an investment, which means that their professional organizations (such as the Association of Research Libraries or the National Council for the Less Commonly Taught Languages) are also involved. The numerous academic disciplines that contribute to A&IS programs, including foreign languages and literature, have an interest. Universities with strong A&IS programs have a stake, as do the presidential associations that represent their interests in Washington (such as the Association of American Universities (AAU)).

Campus-based components of A&IS face internal rivals on campus, however, and these rivalries may be reflected in division within their respective associations. Within key departments, such as history or political sciences, there may be struggles for resources and faculty lines with non-A&IS factions. Within the library, the A&IS collection effort competes with other collection priorities. The language departments may be unwilling to offer less commonly taught foreign languages that are needed by A&IS programs. The entire A&IS community of a university must compete for funding against student aid, faculty compensation, science and technology programs, and other priorities. Even at the national level, the associations and organizations representing the A&IS campus-based community may face internal conflicts over competing priorities, or find themselves lobbying at cross-purposes. In turn, collaboration or conflict at the national level has a significant influence on levels of investment in A&IS.

Additional A&IS knowledge is produced in the USA by government intelligence agencies, military institutions, government-sponsored think tanks, and risk analysts employed by corporations. This information is generally not accessible to the public, and hence is a relatively minor component of A&IS knowledge. These agencies and institutions are important stakeholders, however, as consumers of A&IS information and training, and to a lesser extent, as funders.

The Consumers of A&IS

A second category of stakeholders is constituted by those institutions that need A&IS information or need A&IS-trained personnel. These can be divided in turn into three broad sectors: government, business, and education.

There is a surprising consistency over time in estimates of U.S. government manpower needs for foreign-language and area-trained personnel. The most cited and thorough study is that of James R. Ruchti of the U.S. Department of State, prepared in 1979 for the Perkins Commission, which surveyed more than 25 agencies and concluded that the federal government employed between 30 000 and 40 000 individuals whose jobs required competence in a foreign language, and that, of these persons, between 14 000 and 19 000 were in positions that required skills in the analysis of foreign countries and international issues (Ruchti, 1979, cited at length in Berryman et al., 1979: pp. 75–114). Although estimates of declining government employment have been assumed to reduce the need for foreign-language skills in the federal government, this was not evident in the mid-1990s. The most recent survey of foreign-language needs at 33 federal agencies, undertaken by Stuart P. Lay in 1995, concludes that these agencies have over 34 000 positions that require foreign-language proficiency, of which an estimated 60% are found in the defense and intelligence community (Lay, 1995). Anecdotal evidence suggests that reductions in force since 1995 may have lowered these figures in the nondefense government sectors, but the preponderance of defense and intelligence employment would reduce the effect of such reductions. If 30 000 positions are taken as a possible lower end estimate to account for reductions, and it is assumed that because of the relatively high turnover of military personnel 20% of the federal positions will require replacement in any given year, a replacement need of 6000 government positions per year can be estimated.

Business demand is hard to estimate. Anecdotal evidence suggests that the U.S. business climate has an increased need for A&IS information and skills. In the 1970s, U.S. business was widely seen as uncompetitive on world markets and lagging in productivity. A survey from this period indicates that less than 1% of jobs at 1266 U.S. firms, which accounted for the great majority of industrial exports, required foreign-language skills. Nevertheless, there were 57 000 jobs at these firms that required or benefited from foreign-language skills (Wilkins and Arnett, 1976). Given the predominance of employment in small firms as opposed to large industrial firms, this was clearly an underestimation of private-sector demand at that time.

Adding an equal-sized small-firm component leads to an estimate of about 100 000 positions, which with a 10% turnover would have required replacement of 10 000 positions per year. Since the 1970s, the share of the U.S. gross national product resulting from international trade has quadrupled. It is therefore reasonable to assume that employment in the private sector of personnel with foreign-language and area skills has increased by several magnitudes. Even if such employment has only doubled since the 1970s, the business sector would need to fill 20 000 positions per year involving foreign-language and area competence.

Educational demand for A&IS has been better studied, but not without controversy. The 1970s recession in higher education employment, combined with the Nixon-inspired drop in Title VI funding, led to gloomy projections about the future academic demand for language, international, and area-

trained personnel (see, for example, the extended discussion in Berryman et al., 1979: pp. 30–74). There was also a concomitant reduction in the production of international and area studies PhDs, compared with the 1960s. However, the optimistic projections of the Barber and Ilchman study of 1977 proved more accurate: they noted that tenured area studies faculty were significantly older than the general tenured faculty population, and predicted a surge of retirements over the following 10 years (Barber and Ilchman, 1977). The academic employment market for language and foreign-area specialists was indeed strong during the 1980s.

Another dimension of change in higher education created additional need for foreign-language, international, and area studies faculty, namely the expansion of public-sector undergraduate-teaching institutions, most notably community colleges and branch campuses. The growth of this sector included a substantial and largely unforeseen growth in international education activities, including the teaching of language, international, and to a lesser extent, foreign-area content courses. By the end of the 1980s a sizable proportion of members of the foreign-area studies association were located at undergraduate-teaching institutions.

During the 1990s the demand for postsecondary faculty strengthened. Unemployment among PhDs dropped by more than one-third in the mid-1990s, and all major professional associations, including those in foreign-language and area studies, reported increased postings of job announcements. In part, this reflected the retirement of faculty hired during the higher education boom of the 1960s. Because A&IS grew even more rapidly than higher education as a whole in the 1960s and 1970s, the job market for these specialists was relatively becoming strong through the first decade of the twenty-first century.

Detailed projections of retirement patterns based on the age cohorts of the area studies association's membership were prepared in 1991 by the National Council of Area Studies Associations, which represents the five major area studies associations. Exit rates of present humanities and social science faculty were based on respondents' plans to retire, estimated at 16.9% for 1997 through 2001, and at 16.8% for 2002 through 2007, for a total of 33.7%, or one-third of current faculty. These estimations do not include projections of exits due to morbidity or mortality based on the age structure of the cohorts, which would, if included, lead to an overall exit rate of approximately 40%. Using the latter figure and assuming that exiting faculty are replaced but there is no growth in academic demand, 40%, or 7000, of the current 18 000 area studies faculty will need to be replaced in the first 10 years of the twenty-first century, or 700 positions per year. An additional 1200 positions will be opening in international studies, or 120 faculty positions a year.

Another faculty stakeholder group consists of foreign-language and literature teachers, for whom two sources of information exist, membership in professional organizations, and surveys by the National Center for Education Statistics of the U.S. Department of Education. Using these two sources, a recent study estimates the combined foreign-language and literature faculty in higher education at the start of the twenty-first century at 36 000 persons. If the exit projection of 40% for area studies faculty over the first decade of the new century is applied to the estimated total of 36 000 postsecondary language and literature faculty, an additional 14 000 positions would need to be filled.

Demand and Supply

The demand in federal government, business, and higher education for personnel who have foreign-language skills, and international and foreign-area knowledge will be substantial in the coming decades. Additional demand from state and local government and from secondary education may also be expected. Overseas employment offers another, as yet unexplored, source of demand. Annual demand for the first decade of the twenty-first century is estimated at 20 000 business jobs, 6000 government jobs, and 10 000 education jobs, for a total of 36 000 foreign-area, international, and language-trained personnel.

The supply side of the equation is far simpler to estimate, as are the implications for Title VI legislation. The number of federal Foreign Language and Area Studies (FLAS) Fellowships awarded annually through Title VI of the HEA, which was 600 in 2000, does not meet even the academic demand, although it is a stimulus for recruiting superior students. The overall annual production of PhDs by Title VI centers was about 1400 per year in the early 1990s. Beginning in 1993 there was a substantial increase in the number of universities receiving National Resource Center for Foreign Language and Area Studies (NRC) or FLAS funding, leading to a jump of PhD production to about 1900 language- and area-trained personnel (Schneider, 1995b). These numbers, which have since been stable, are less than the estimated annual higher education demand for 2100 foreign-language or area studies faulty over the first decade of the twenty-first century.

The production of MA degrees by Title VI centers is higher, averaging about 6000 per year in the 1990s (Schneider, 1995b). That number is far below the annual combined demand for about 14 000 persons coming from the K-12 education sector and the federal government. Production of BAs by Title VI centers approximated 27 000 students annually by the early 1990s, of which an estimated 6000 enter graduate school, and 21 000 of the BA graduates enter the job market. Of the 6000 MA recipients, about 2000 continue graduate study and 4000 enter the market. Thus a combined total of 25 000 BA and MA graduates with foreign-language or area training enter the job market, compared with a demand from business, government, and K-12 education estimated above at 34 000 positions. These positions must be filled by persons trained in other programs or on the job.

As a consequence of the shortfall of trained personnel, the federal government spends considerable sums of money on in-house training programs, such as the Department of Defense's Defense Language Institute (DLI), the National Security Agency's National Cryptologic School (NCS), and the Department of State's Foreign Service Institute (FSI). The DLI and the NCS together train about 4600 students annually. In 1995, for example, the Department of Defense alone spent over $78 million to train linguists to meet its need, considerably more than the cost of all Title VI programs that year (Lay, 1995: p. 1). In-house foreign-language training at the FSI cost an

additional $10 million. These figures do not include the salaries of the personnel who are being trained.

The Investors in A&IS

Investment in A&IS in most of the world is supported almost exclusively by national governments. In the United States, funding for A&IS has come from the federal government, but also from two other sources – private foundations, and from colleges and universities themselves. Title VI of the HEA, formerly the National Defense Education Act (NDEA), administered by the Department of Education, has been the primary instrument through which the federal government supports A&IS (cited in McDonnell et al., 1981: p. 11). Beginning in the mid-1990s, the National Security Education Act provided additional support through the Department of Defense.

The history of A&IS has been of a roller coaster. Federal funding was critical to the development of A&IS in the United States, but has been threatened or reduced a various times. Foundation funding was highly important at one time, but was later reduced to modest levels. Despite this variation of support through time, the commitment of higher education institutions support for A&IS, once established, has proven relatively constant.

The original rationale for NDEA as a whole was narrow and clearly articulated: "To insure trained manpower of sufficient quality and quantity to meet the national defense needs of the United States" (cited in McDonnell et al., 1981: p. v). In the post-Sputnik atmosphere of concern about Soviet achievements in science and technology, the NDEA legislation focused primarily on training in the physical sciences and engineering. However, *prior* to Sputnik the U.S. Office of Education had prepared draft legislation on foreign-language and area training. This legislation, according to one contemporary official, had been drafted because, "By the mid-1950s responsible people in the Government were beginning to realize that university resources in non-Western studies were wholly inadequate to meet present and anticipated national needs. Some measure of Government assistance to language and area studies seemed essential" (Mildenberger, 1966: pp. 26–29).

The Office of Education's foreign-language and area studies draft was incorporated in the NDEA bill as the result of negotiations between Assistant Secretary of Health, Education, and Welfare, Eliot L. Richardson, on behalf of the Eisenhower Administration and the sponsors of the legislation, Senator Lister Hill and Representative Carl Elliott (Clowse, 1981). Like all sections of NDEA, the original Title VI emphasized training, in this case of individuals in modern foreign languages "needed by the Federal Government or by business, industry, or education" and "not readily available in the United States." Such individuals were also to be trained "in other fields needed to provide a full understanding of the areas, regions, and countries in which such language is commonly used," including "fields such as history, political science, linguistics, economics, sociology, geography, and anthropology" (NDEA of 1958, as Amended, reproduced in Bigelow and Legters, 1964). In subsequent legislation, Fulbright-Hays 102 (b)(6) was added to Title VI to provide funding for overseas training components, such as doctoral dissertation research abroad.

The original NDEA Title VI legislation envisioned a 50–50 partnership in which the costs of foreign-area centers would be divided equally between the universities and the federal government (a munificent arrangement in comparison to the 20:1 ratio of university to federal support for Title VI centers at the time of writing) (McDonnell et al., 1981: p. 38). Federal support for foreign-area studies was augmented by sizable investments from the philanthropic community, led by foundations such as Ford, Rockefeller, Mellon, Carnegie, and Tinker. The Ford Foundation alone contributed about $27 million annually between 1960 and 1967 for advanced training and research in international affairs and foreign-area studies, more than federal appropriations for Title VI in the same period.

The establishment of foreign-area programs was a costly venture for universities even with federal and foundation subsidies. Yet universities responded to NDEA Title VI with enthusiasm. This reflected a consensus between academia and government on national needs in the field of international education, forged by World War II and reinforced during the early stages of the Cold War. Many, if not all, foreign-area scholars, university administrators, and foundation executives had served in State Department, intelligence, or military positions during World War II or the Korean War. The boundaries between government and academic institutions were permeable and amicable. The relatively small size of the community of foreign-area specialists inside and outside government meant that people knew one another. Perhaps most important of all, they shared a similar perspective on the U.S. role in world affairs. The alliance between academia and government for foreign-area training and research was a natural outgrowth of these affinities.

The Title VI experiment proved highly successful. Within a decade the United States had established a network of centers covering most foreign areas, generating unprecedented quantities of research, and producing substantial numbers of new foreign-language and area specialists. Ancillary institutions such as foreign-area studies associations and research journals multiplied quickly. The prestige and the funding conveyed by Title VI designation continued to be rewarded by university administrations (Merkx, 1990: pp. 1, 18–23).

Following the promising early start of Title VI came the Vietnam War, which by the late 1960s led to funding freezes and then to declines. Moreover, the Vietnam War itself produced a significant deterioration in the relationship between government and academia. Academic dissent from U.S. foreign policy in Southeast Asia began to grow during the Johnson Administration and reached high levels during the Nixon Administration. The events of Watergate did little to increase academic confidence in government. Resentment by government officials of criticisms from academia, including from some of the very foreign-area specialists trained under Title VI, grew as well. The gradual retirement of the World War II generation of leaders further contributed to the growing gulf between academic and government cultures.

The Carter Administration made some effort to improve relations with the academic community. Carter appointed a Presidential Commission on Foreign Language and International Studies (known as the Perkins Commission), which in 1979 issued a strong call for increasing federal support of international education to more than three times existing levels

(US Department of Health, Education, and Welfare, 1979). Among its recommendations were the establishment of undergraduate and regional foreign-area centers as complements to the Title VI national resource centers, and the provision of annual federal grants of $50 000 to each of the national resources centers for library costs. However, the timing of the Perkins Commission report was not propitious. Double-digit inflation and high interest rates were leading to reductions, not increases, in federal expenditures.

A more successful initiative by the Carter Administration was to repeal NDEA and incorporate its Title VI functions in a new HEA. This step ratified the separation of university-based foreign-area studies from the national defense needs that had been the original justification for federal funding. While pleasing many campus-based area specialists, the change of name made Title VI a more vulnerable target for those in the next administration who were to argue that federal subsidies were no longer in the national interest.

The years of the Reagan Administration represent the nadir of the partnership between academia and government in foreign-area studies. Due to the high inflation of the late l970s and early 1980s, and essentially level funding in current dollars, Title VI appropriations in real terms were at their lowest level since the inception of the program, falling to well below half their 1967 high point. The Administration was formally opposed to the program. Higher education in turn was suffering from the consequences of inflation, the growth of university enrollments had taken a sharp downturn for demographic reasons, and foundation support for international education had evaporated.

Nonetheless, the partnership between government and academia survived. Support for Title VI came from three directions. A few well-placed government officials recognized the value of Title VI research and training, and were moved to intervene on its behalf. A second source of support came from the directors of Title VI-funded area centers, who were galvanized by the realization that the survival of Title VI programs could no longer be taken for granted. The second-generation center directors of the 1980s lacked the Washington contacts and political knowledge of the founding generation. They were forced, however, to increased activism by the disastrous implications of a total cutoff of federal support for their programs. After the failure of their efforts to reverse the Reagan Administration zero-funding of Title VI in the early 1980s, the center directors focused on the Congress. These early attempts at congressional relations were for the most part uncoordinated individual initiatives, but were not without effect. Congress proved more responsive to the universities than the administration had been, and Title VI funding survived.

The third source of support came from individuals outside of government and academia that were affiliated with institutions involved directly or indirectly with international education, such as the major foundations, higher education associations, and professional organizations.

The growing sense of shared concern about the chronic underfunding of international education in general, and the threat to Title VI in particular, coalesced in an initiative that began with a dinner at the Smithsonian Institution in late 1984 "to discuss what might be done to stabilize long-term federal support for international studies and foreign language training" (Prewitt, 1986: p. v). Several foundations funded, under the aegis of the AAU, a study which resulted in the monograph *Points of Leverage: An Agenda for a National Foundation for International Studies* (Prewitt, 1986: p. v), accompanied by the recommendation of an AAU advisory committee chaired by Kenneth Prewitt of the Rockefeller Foundation (AAU, 1986). The Prewitt committee offered draft legislation for the establishment of a National Foundation for Foreign Languages and International Studies.

The AAU Legislative proposal was intended to serve as a rallying point for the various international education constituencies. It had the opposite effect. The proposal was viewed with suspicion as being the product of the elite institutions associated with the AAU. It was widely misinterpreted as constituting a threat to existing programs. The process by which the proposal was developed was criticized for having too narrow a base and not including a sufficiently broad spectrum of international education interests.

In a constructive response to these criticisms, the AAU obtained additional foundation support to broaden the dialogue about international education needs, establishing in 1987 a 2-year effort known as the Coalition for the Advancement of Foreign Languages and International Studies (CAFLIS). An open invitation to participate was sent to virtually every type of group that might be interested. Ultimately, some 150 organizations participated in one or more stages of CAFLIS discussion, including most higher education associations, area studies associations, language groups, organizations engaging in foreign exchanges, peak organizations in the social sciences, and professional associations.

Despite, or perhaps because of, the inclusive nature of the process, CAFLIS ultimately ended in failure. The various constituencies represented in the CAFLIS process had different agendas and found difficulty coming to an overall agreement. A fundamental cleavage existed between those groups that emphasized the need for increased investment to meet the original Title VI goals of advanced training and research in foreign-language and area studies (a focused and less costly agenda), and those who were advocating federal subsidies for language training in primary and secondary schools, for internationalization of undergraduate education, or for adding international dimensions to professional training in fields such as business, medicine, and engineering (a diffuse and more costly agenda).

The disappointing outcomes of both the AAU legislative proposal and the CAFLIS process led the core A&IS groups to refocus attention on Title VI. The HEA was to expire in 1990. The AAU, the National Association of State Universities and Land Grant Colleges, and the other higher education presidential associations organized a series of meetings on Title VI reauthorization that culminated in the appointment of an Inter-Association Task Force on HEA–Title VI Reauthorization. The directors of foreign-area centers receiving federal funding formed a Council of Title VI National Resource Center Directors (CNRC). The foreign-area studies associations organized a coordinating group of executive directors and presidents known as Council of Area Studies Associations.

This resurgence led to a strategy of building support for Title VI programs in particular, and A&IS in general, by mobilizing

the campus-based core constituencies, their professional associations, and national organizations such as the AAU. At the invitation of CNRC a meeting of all these groups took place at the Library of Congress in 1991, for the purpose of defining a common agenda with respect to Title VI reauthorization. When the final law reauthorizing HEA was approved by the Congress in 1992, Title VI incorporated, virtually intact, almost all of the recommendations of the Inter-Association Task Force which had been supported by the core constituencies.

This success of the 1991–92 reauthorization effort resulted in the establishment of the Coalition for International Education, which includes 26 national organizations representing the various A&IS stakeholder communities. This membership includes six higher education associations representing college and university presidents, two associations of international education administrators, four associations of Title VI-funded program directors (representing area centers, business centers, language centers, and schools of international administration), two library associations, two international exchange associations, one council of overseas research centers, one area studies association, a social science association, a humanities alliance, an overseas university, and an association of graduate schools.

Federal funding for A&IS reached a low point in constant dollars during the mid-l980s. Following the establishment of the Coalition for International Education, appropriations grew steadily. Adjusted for inflation, funding for Title VI grew 6.5% between the 1994 and 2000 federal budgets. The original Title VI programs, such as the area centers, are funded at about one-half their constant dollar figures of the late l960s. The overall International Education and Foreign Language Studies account in the year 2000 federal budget was approximately $70 million. In the first decade of the twenty-first century, Title VI appropriations grew more rapidly, reaching a high point in FY 2010 of $125.7 million. However, the FY 2011 appropriation was reduced by $50 million to $75.7 million. It declined to $74.2 million in FY 2012, and was restored to $75.7 million for FY 2013. The political stalemate in Washington at the start of the second term of the Obama Administration does not bode well for restoring the cuts in the Area and Foreign Language (A&FL) programs of the Department of Education.

Abstract

Area studies are the systematic efforts of knowledge production about particular world-regions through academic institutions often used to inform foreign policy strategies of national governments. Their history is a classic example to show the interrelatedness between the political history of the Cold War and the intellectual history of the social sciences in the twentieth century. This article outlines the emergence of area studies in the Soviet Union and the United States of America before turning to more recent trends and criticisms that characterize the field until today.

Introduction

The history of area studies is a particularly illustrative example for the interrelatedness of the intellectual history of the social sciences and the political history of the twentieth century. Area studies are the systematic efforts of knowledge production about particular world-regions through academic institutions often used to inform foreign policy strategies of national governments. Within the realm of foreign policy analysis, area studies were supposed to provide familiarity with various local contexts in the non-Western world through linguistic, historical, cultural, sociological, economic, and political research that usually relied on extensive field experience in the respective countries. In that, they explicitly challenged disciplinary boundaries in the social sciences while emphasizing an integrative interdisciplinary approach to a geographically limited space. The definition of area boundaries and allocation of resources always mirrored the geopolitical interests of the powers behind these endeavors. African studies, Russian and Soviet studies, North American studies, East European studies, Near or Middle Eastern studies, South Asian studies, Southeast Asian studies, East Asian studies, and Latin American studies denote some of the most typical research fields of area studies institutions.

Area studies have typically been described as a US-American Cold War enterprise (*see* Cold War: Impact on Social and Behavioral Sciences). Having evolved from the extensive use of scientific research groups in military, government, and intelligence agencies during World War II, area studies centers and departments were one of the institutional offsprings of interdisciplinary policy-oriented social science research organizations exemplifying the close relationship between the sciences and politics in Cold War America. While it might be true that no other nation has yielded area studies in comparable scope and breadth as the USA did during the Cold War years (Szanton, 2004: 8), the history of area studies can neither geographically nor temporally be reduced to Cold War America. The case of the Soviet Union shows how Russia's colonial tradition in Oriental studies has been reorganized toward politically more useable knowledge production about its peripheral and neighboring cultures already during the 1920s in a way that is remarkably similar to U.S. area studies 20 years later. Furthermore, area studies have not lost their significance since the Cold War has ended.

Area studies' uncomfortable position between the diverging normative demands from political and scientific institutions was at the heart of many controversies concerning the ethics of applied social science. At best, area scholars drew theoretical and methodological innovations from their high degrees of entanglement with actual political processes and institutions that fed back into the social science disciplines in fruitful ways. At worst, area scholars were part of highly questionable intelligence operations without any scientific value.

This article begins by outlining the development of area studies in the Soviet Union since the 1920s, followed by a discussion of the situation in the USA. In both cases, emphasis is laid on its developmental phase and in particular on the interplay between the political context and the intellectual history of area studies. Finally, the field's diversification including its central conflicts and criticisms will be reviewed and current trends be traced (for detailed accounts *see* Area and International Studies in the United States: Stakeholders; Ethical Questions in Social and Behavioral Sciences, history of; Funding of Social Science, History of; Modernity: History of the Concept; Cold War: Impact on Social and Behavioral Sciences; Counter insurgencies and the Social Sciences; Western and Non-Western Views of the Social and Behavioral Sciences: De-Westernizing the Social and Behavioral Sciences). Due to the field's tremendous diversity, a limited number of examples will serve to illustrate the general problem of area studies as much as some specific problems that resulted from this influential and often controversial field of scholarship.

Area Studies in the Soviet Union

Oriental Studies in the Interwar Period

Soviet foreign area scholarship had its roots in the tsarist Russian empire where studies of the languages and cultures of 'the Orient' have a long tradition that reaches back into the eighteenth century. By the turn to the twentieth century, the Institute of Oriental Studies of the Russian Academy of Sciences in St. Petersburg, founded in 1818, was Europe's leading research institution in the field (Schimmelpenninck van der Oye, 2011) housing linguistic and historical specialists on a vast geographical area from Northern Africa, the Middle East, and the entire rest of Asia, including Russia's own territories in Central and Eastern Asia. From the beginning, this institution had advisory functions to the tsarist regime. After the Russian Revolution in 1917, however, Oriental studies were fundamentally reorganized in order to meet the new political requirements of the Bolshevik regime.

In its historical mission to spread the Communist revolution across the world, the Russian Communist Party redirected its foreign policy priorities to the Middle East, after revolutionary attempts had failed in Europe in the aftermath of World War I. As early as in 1919, Leon Trotsky advocated a strategy to destabilize the bourgeois regimes in Europe by instigating national revolutions in the Middle East against the European colonial powers. This emancipatory revolutionary agenda for the Oriental peoples constituted the political basis for Soviet area studies in North Africa and Asia during the interwar period and beyond.

The St. Petersburg (then called Petrograd) Institute of Oriental Studies was skeptically viewed by the Bolshevik leadership due to its historical legacy as a bourgeois research institution and its former ties to the tsarist regime. Therefore an additional Institute of Oriental Studies was established in Moscow in 1921 that became the primary institution to train political, administrative, diplomatic, and educational personnel for the Soviet state in questions regarding the Orient for several decades (Kemper, 2011: 3). Besides doubts in the political loyalty of the Petrograd Institute, the Moscow Institute was to replace Petrograd's emphasis on classical languages and history by contemporary social sciences that were able to provide politically immediately useable skills and knowledge.

Key event for the new Soviet Oriental studies was the Congress of the Peoples of the East held in September 1920 in Baku/Azerbaijan where leading politicians and intellectuals from Oriental countries including Azerbaijan, Daghestan, Central Asia, Iran, and Turkey convened to corroborate the Soviet Union's alliance with anticolonial revolutionary movements in the Middle East (Kemper, 2010: 448). Oriental studies, in this situation, had the double function of systematically generating knowledge about the local conditions in the Oriental countries for the Soviet elite and creating a national political consciousness among, what was called, the uneducated masses of the Orient, which would finally lead to revolution. The second rationale is especially visible in the plan to establish a University of Social Sciences for Workers of the Orient in Baku, comprising training in history and culture, geography and ethnography, economy, legal sciences, socialism, and revolutionary movements in the East. Additionally to this social science education, the designated curriculum allowed for specializations in a specific country (Kemper, 2010: 454). Though never realized in Baku, two Moscow institutions, the Communist University of the Toilers of the East (1921) and the already mentioned Institute of Oriental Studies (1921) were built in accordance to these plans, educating both Oriental and Russian students in Oriental languages and social sciences.

As the intellectual key figure of early Soviet Oriental studies emerged Mikhail P. Pavlovich (1871–1927), a former Menshevik intellectual who gained a reputation as a theorist of revolutionary movements in Africa and Asia (Kemper, 2010). Having held advisory positions in the young Soviet state before, Pavlovich became chairman to the newly funded All-Russian Scientific Association of Oriental Studies (Vserossiiskaia Nauchnaia Assotsiatsiia Vostokovedeniia, VNAV) in Joseph Stalin's People's Commissariat for Nationalities in December 1921 and director of the Moscow Institute for Oriental Studies in 1923. Different from the Baku initiative with its direct revolutionary purpose, the VNAV was designed to coordinate scholarly activities in Oriental studies throughout the Soviet state. Its purpose was to inform policy makers as much as the broader public. Quickly, it published a journal called Novyi Vostok (New Orient, 1922–30) and opened a number of new branches during the 1920s from the Ukraine to Siberia (Kemper, 2010: 455f.).

Intellectually, early Soviet Oriental studies were mostly concerned with determining the historical stage within the Marxian development model on which the Oriental peoples were to be located and what role Islam played in that process. In accordance with the Comintern's interwar strategy to support national identity policies (*korenizatsiia*) in order to gain popularity within the peasant and workers' masses, Islam was initially seen far less critically than Christian orthodoxy in Russia. By the 1930s, however, with the political repressions escalating toward Stalin's Great Purge, moderate views on religion became gradually impossible to express. Many Orientalists suffered severe repression, imprisonment, forced labor, and execution (Kemper, 2011: 6–8). With the German attack on the Soviet Union in 1941 and the subsequent devastating war, the situation further aggravated. Political repression and censorship continued after the war and culminated once again in Stalin's xenophobic campaign against 'cosmopolitanism' during the early 1950s. Only after Stalin's death in 1953 did Soviet area studies enter into a phase of institutional and intellectual consolidation and diversification.

Diversification of Area Studies in the Soviet Union during the Cold War

With the expansion of the Soviet Union's global activities during the Cold War, its area studies programs expanded in geographical scope too. North American studies, lacking prewar traditions in Russian scholarship, emerged in the Soviet Union during the 1950s and 1960s as a distinct field. The first important center for the study of North America was located at the Institute for World History at the Russian Academy of Sciences. Besides its interest in American foreign policy, especially with respect to US–Russian relations as well as U.S. policies in Latin America and the Far East, Soviet Americanists paid much attention to the emergence of capitalism in the USA, the history of slavery, and in particular the study of African Americans in past and present (Bolkhovitinov, 1969). The second was the Institute for US and Canadian Studies at the Russian Academy of Sciences (ISKRAN), whose founding director from 1967 to 1995 was the political scientist Georgy Arbatov (1923–2010). Different from its counterpart at the Institute for World History whose members' often maintained a critical distance to the Soviet regime (Zhuk, 2009), ISKRAN's work has been very close to foreign policy decision-making with Arbatov personally advising all General Secretaries of the Communist Party of the Soviet Union since Leonid Brezhnev (1964–82).

Institutes for African Studies (1960) and Latin American Studies (1961) (Westad, 2007: 68) completed the geographical scope of area-specific research organizations in the Soviet Union. In all cases, these institutions prepared briefs for Party and intelligence agencies and their research agendas displayed the political and ideological interests of the Soviet regime. Special attention has been given to national liberation movements and decolonization (Desai, 1968: 252). The ubiquitous

criticism of American foreign and domestic policies reveals that area studies also fulfilled an important propagandistic function. Nevertheless, Soviet area studies centers produced valuable scholarship that received appreciation also among Western colleagues (Bartley, 1970). Though rigorously surveilled by the Komitet gosudarstvennoy bezopasnosti (KGB, Committee for State Security), Soviet area scholars increasingly engaged in fieldwork in all world areas, including the USA.

Area Studies in the United States of America

World War II and the Origins of Area Studies in the USA

In US-American scholarship knowledge about the non-Western world was hardly available in any organized fashion prior to World War II (cf Chomsky, 1997), possibly with the exception of the rather small community of cultural anthropologists. With the United States entering the World War II in December 1941, however, background knowledge on historical, cultural, and political issues in a variety of Western and non-Western countries suddenly became urgently needed. Various military and government agencies began seeking support from scientists. Most notably, the Office of Strategic Services (OSS) and the Office of War Information (OWI), the prime wartime institutions for intelligence and propaganda, created large and well-organized research units that recruited scholars from various social science disciplines and the humanities from the top universities in the US and abroad (Katz, 1989). Additionally, the Army Specialized Training Program was launched at 227 U.S. universities by the end of 1942 to train military personnel in various specializations, among them specific area and country education at 55 campuses (Lambert, 2001: 687).

Besides language training, a certain familiarity with cultural specificities was considered necessary which gave cultural anthropologists an opportunity for war-related activities. John M. Cooper estimated that 'probably a good half' of American professional anthropologists, engaged in 'full-time war activities' during World War II (Cooper, 1947: 2). The two most outstanding figures in this respect were Margaret Mead, working, among other things, on the improvement of war propaganda and Ruth Benedict, who contributed the famous study on Japanese culture *The Chrysanthemum and the Sword: Patterns of Japanese Culture*, first published in 1946 (Mandler, 2012). Commissioned by the OWI in June 1944 in light of a planned U.S. occupation of Japan, Benedict produced a comprehensive account of Japanese culture in order to predict Japanese reactions to military intervention and a possible occupation scenario after the war. While influencing American views on Japanese culture for decades to come, the study indicates how social science knowledge could be used in foreign policy decision-making. Characteristic features of wartime social science research in government organizations were interdisciplinary research teams, a keen focus on analysis and solution of concrete policy problems and close attention to the local particularities. In that sense, McGeorge Bundy later called the OSS the 'the first great center of area studies' in the USA (Engerman, 2009: 3). The importance of this kind of research for intelligence agencies was mirrored in the Central Intelligence Agency's (CIA) continuation of OSS's Research and Analysis Branch after the war (Müller, 2010).

Postwar: Institutional Takeoff

By the end of World War II there was a broad consensus in US-American science and policy circles that general knowledge about the non-Western world was in a very poor state and that the new international role the United States had achieved in the course of World War II required massive investment in producing such knowledge. The Soviet Union solidifying its strength in Europe and Asia, the rise of China as another Asian giant, and early signs of decolonization in Asia and Africa were perceived as the threats that necessitated this investment. In this situation, international and area studies had the function to provide 'culturally and historically contextualized knowledge' about world-regions of political interest (Szanton, 2004: 10).

This governmental impetus notwithstanding, postwar area studies were primarily organized by nongovernmental organizations, above all the Social Science Research Council (SSRC) and the American Council of Learned Societies. Funding has been predominantly provided by the universities themselves though only through contributions from a number of private foundations could the additional financial needs for language training and overseas research be met. Among them, the Ford Foundation stood out as the single most important organization, investing more than $ 270 million only between 1951 and 1966 and funding 2.050 doctoral students between 1951 and 1972 (Szanton, 2004: 11). Other organizations included the Rockefeller and Mellon Foundations or the Carnegie Corporation. Government funding became an additionally important factor with the 1958 National Defense Education Act (NDEA) following the Sputnik shock the year before. Title VI of NDEA and later the Higher Education Act established language and area programs as recipients of government support. Together, these institutions were able to trigger a massive expansion of area studies organizations across the United States. Almost inexistent before World War II, area-specific curricula have been offered at nearly every second university in the United States by the 1990s (Lambert, 2001: 687; *see* Area and International Studies in the United States: Stakeholders; Funding of Social Science, History of).

Two institutional forms have emerged in area studies training: area studies centers and area studies departments. The latter were modeled after wartime organizations and offered interdisciplinary training including languages, literature, history, religion, and occasionally politics on undergraduate and graduate level. Area studies centers (or institutes and programs respectively), on the other hand, were designed for students who have been trained in one of the social science disciplines before, among them anthropology, art history, geography, history, language and literature, music, sociology, political science, and others. This type gained importance during the 1960s and dominated the field since the 1970s typically resulting in double identities of area scholars with regards to their home disciplines and the region they specialized in (Szanton, 2004: 7).

Early Russian or Soviet Studies

World War II ended in the bipolar world order of the emerging Cold War between a Western and an Eastern bloc with the USA and the Soviet Union as their respective leaders. Not surprisingly, Russian or Soviet studies immediately emerged as the

first full-fledged field of area studies in the USA. Three centers stand out particularly for the early phase of US Soviet studies. The first was the Russian Institute (RI) at the Columbia University, opening as early as in 1946 with the support of the Rockefeller Foundation and working closely with the U.S. army and navy. The second was the Russian Research Center (RRC) at Harvard, established in 1948, getting most of its support from the CIA and the air force (Engerman, 2009: 7). The third major center of early Soviet studies in the USA was the Center for International Studies (CENIS) at the Massachusetts Institute of Technology (MIT), founded in 1951, receiving significant support from the CIA too. Together, these centers display the field of early Russian and Soviet studies, which shows strong personal and institutional continuities with wartime research experiences and in which entanglements with government and intelligence agencies were exceptionally close.

Columbia's RI, with eminent historian Geroid T. Robinson the only center having an expert on Russia as its director, was the politically most diverse center of the three, including open admirers of socialism and the Soviet Union. Unusual for this early phase of American Soviet studies, the RI was able to send researchers to the Soviet Union for conducting fieldwork. During the rampantly anti-Communist McCarthy era, this fueled suspicion about the faculty's loyalty to the anti-Communist stance of U.S. foreign policy. While being largely insignificant in publishing research on the Soviet Union, the RI's credentials lay in its important efforts to build the academic infrastructure for US-American Soviet Studies. It was by far the most productive institute to train experts on the Soviet Union for government service and, primarily through the Joint Committee on Slavic Studies, to secure library facilities, access to Soviet newspapers and periodicals, and to collect the existing academic literature on Russian affairs in the USA. Therefore, Columbia's RI has "rightfully claimed to be the founder of modern Russian Studies in the United States" (Engerman, 2009: 13–42, here: 36).

Upon its inauguration, Harvard's RRC could already benefit from the research infrastructure set up by the RI. In contrast to Columbia, however, the RRC assembled social scientists with strong disciplinary backgrounds rather than prior research experience in or about the Soviet Union and displayed a general leaning toward the emerging paradigm of behavioral science. Its first director was Clyde Kluckhohn, an anthropologist who established his reputation in the OWI's Foreign Morale Analysis Division during World War II where also Ruth Benedict's study on Japanese culture originated. Though variously involved in government-sponsored projects, the RRC was successful in maintaining some degree of scholarly distance to politics and established itself as the leading research center on Soviet affairs in the USA.

Probably the most conspicuous example of intelligence sponsored academic research related to area studies was the CENIS at the MIT. The MIT had been heavily engaged in wartime research for government and intelligence agencies and has continued to work on classified and secret research projects during the years that followed World War II on a regular basis. One offspring of this political entanglement was Project Troy, a 3-month top-secret research project funded by the State Department in autumn 1950 to explore US-American possibilities for propaganda actions behind the Iron Curtain including technical and social science perspectives. The 21 distinguished scholars in Project Troy found their work a stimulating experience and suggested to establish an organization dedicated to Cold War social research. Their recommendations led to the establishment of CENIS in 1951 (Needell, 1998). Its intellectual core group was composed of economists around Max Millikan and Walt Whitman Rostow who, not being experts on the Soviet Union, quickly developed research interests in international economics and foreign policy more broadly (Blackmer, 2002).

Diversification and Liberalization of Area Studies

Russian or Soviet studies' intimate entanglements with American Cold War foreign policy, including covert intelligence operations, illustrate the aspect of political application orientation in the service of governments that is inherent in the area studies approach. From the beginning of area studies during World War II, however, its proponents also pursued another objective: the deprovincialization of US-American higher education (*see* Western and Non-Western Views of the Social and Behavioral Sciences: De-Westernizing the Social and Behavioral Sciences). Different from the political instrumentality of social science research, this argument emphasized the epistemological benefits of accounting for the plurality of worldviews in a globalizing world. With the higher education sector drastically expanding and the parallel politicization and liberalization of American universities during the 1960s, these two objectives increasingly seemed incompatible with each other.

Area studies' principle to institutionalize in-depth knowledge of non-Western cultures essentially favored interpretative social science disciplines and could only meaningfully be realized through extensive fieldwork. The Ford Foundation's prestigious Foreign Area Fellowship Program, established in 1950, was the most important institution to enable doctoral students to gain the necessary familiarity with the countries they specialized in. Although area scholars have continuously worked with government and intelligence agencies, these activities naturally remained limited in number. With area studies centers proliferating across the USA, most of these institutions had no direct involvement with the government and emphasized academic research instead.

With African studies, Asian studies, and Latin-American studies, area studies quickly diversified its geographical scope. Instead of the 'Know your enemy'-approach prevalent in Russian or Soviet studies (Engerman, 2009), these fields usually encompassed more sympathetic attitudes toward the peoples and cultures they studied, engaged in intensive exchanges with local scholars and often turned expressly critical toward US-American foreign policies in their respective regions. Two events stand out as particularly important that changed the public and professional understandings of the roles social scientists took in foreign policy-related research.

In 1965, the disclosure of Project Camelot brought the topic of government-sponsored social science research to widespread public debates. Planned within the Special Operations Research Office in the American University and the U.S. Department of Defense, the purpose of the project was to "measure, predict and control internal conflict within peripheral countries" (Navarro, 2011: 807) through a series of

case-studies across the world and was to be implemented in Chile. After failing attempts to recruit Chilean social scientists for it, the project had been first publicly discussed in June 1965, which caused massive reactions in Chile, the US and beyond that saw an unacceptable political agenda behind it. Eventually, what was to become "the largest social science project in US history" (Solovey, 2001: 171) was canceled before it actually got started. More generally, the disclosure of Project Camelot fueled already existing discussions about the relation of social science research and espionage and the impact of government funding on the autonomy of the social sciences (*see* Counter Insurgencies and the Social Sciences; Ethical Questions in Social and Behavioral Sciences, History of).

The increasingly critical attitudes of area scholars toward the involvement of their profession in U.S. foreign policy culminated during the escalation of the Vietnam War. In 1968, a group of young Southeast Asian scholars from various area studies centers in the USA formed the Committee of Concerned Asian Scholars (CCAS) in order to express organized protest from within their academic field against the U.S. warfare in Vietnam and the role area scholars had played in it. In particular, the CCAS founding statement criticized the "complicity or silence of [their] profession with regard to that policy" in Asia that served expansionist interests of the USA. Instead, they demanded from Asian scholars to take 'responsibility for the political consequences of their research' and stressed the need to "develop a humane and knowledgeable understanding of Asian societies" instead (Committee of Concerned Asian Scholars, 1969).

Intellectual Trends

With respect to the academic disciplines, area studies stood for strengthening the social sciences as politically engaged applied science – be it in the service of governments or of marginalized groups – and openly challenged traditional disciplinary differentiations in a way that transformed the relations of the disciplines with each other in significant ways (Wallerstein, 1996). Though practically all social science disciplines were represented in area studies in one way or another, their degree of involvement differed.

Psychology, for example, being of central importance to many interdisciplinary endeavors in the social sciences during the early postwar period (Backhouse and Fontaine, 2010), played only a minor role in area studies. While being relevant to certain streams in Russian or Soviet studies, the general tendency of most area studies centers to emphasize the study of cultural particularities stood in opposition to psychology's attempts of establishing a universalist science of human behavior.

Economics, another discipline often cited to have championed the universalist tradition in social science, has produced area specialists especially within its branch of development economics. Modernization theory is maybe the most distinct outcome of economists, and to a lesser degree, political scientists and sociologists, engaging with area studies (*see* Modernity: History of the Concept). Dependency theory and other critiques of development theories are good examples of the dynamics that the engagement of Western social science with non-Western regions and their local scholarly communities evoked (Drake and Hilbink, 2004). The dominance of neoclassical theory, however, made economics play no important role in area studies since (Szanton, 2004: 7).

The disciplines that could establish themselves most firmly in area studies were anthropology, geography, history, literature, sociology, and political science. In all cases, the most innovative impulses were drawn from the confrontation of established concepts from the social science disciplines with in-depth studies in non-Western regions. Increasingly, contributions from scholars from the regions studied gained importance, which sometimes resulted in explicit critiques of the area studies approach itself. The best example for this might be the emergence of Subaltern studies which radicalized the idea of prioritizing the epistemological position of marginal rural populations as opposed to the elite-centered view prevalent in conventional South Asian studies (Dirks, 2004; Guha and Spivak, 1988; Chakrabarty and Bhabha, 2002). Such developments together with rising numbers of students with cultural and ethnic backgrounds from the respective regions inside Western universities contributed to area studies' promise to deliver culturally sensitive knowledge about the non-Western world.

Criticisms and Newer Trends

Besides criticisms referring to the political instrumentalization of area studies for an imperialistic U.S. foreign policy (cf Simpson, 1998), area studies were also criticized on academic grounds. A common argument has been the accusation of being passive consumers of the methodological work done in the core disciplines resulting in a generally inferior quality in scientific standards. This accusation was often coupled with the more far reaching blame for adhering to a merely 'idiographic' research style that confines itself to collecting curiosities from remote world areas without developing generalizable theories. Naturally, this criticism was especially audible from scholars and disciplines that championed universalist approaches to social science, especially dominant in psychology, economics, and political science. Set aside the deeper philosophical discussion about universalism versus particularism in the social sciences, this argument cannot be upheld as an accusation to area studies in general. First, universalist approaches were not absent in area studies centers as has been shown above. Second, the increasing particularist leaning in area studies did not mean absence of theoretical generalizations. To the contrary, area studies most innovative moments emerged from reappraising established theories in the light of new empirical work outside the context where the theories were initially developed.

Another line of criticism has been launched from the epistemologically opposite camp. Poststructuralist and postcolonial theorists have accused area studies of reproducing an imperial perspective on the areas they have been studying by adhering to an established Western conceptual apparatus. Instead, they insisted that cultures could only be studied in a nonhegemonic fashion if they are analyzed in their own terms. Area studies self-understanding of 'translating' foreign cultures to a Western audience (Mirsepassi et al., 2003), even when detached from direct political or developmentalist projects, inevitably contained a sharply asymmetric distribution of power between those studying and those studied. This criticism, most famously related to Edward Said's critique of Orientalism (1978), has been largely endorsed by many area scholars and has become extremely influential since the 1980s.

The relation between power and epistemology inherent to the program of studying non-Western cultures within Western academic institutions has since been excessively debated and constitutes a dominant theme in today's literature on area studies in general.

With the Cold War coming to a sudden end by the end of the 1980s, a third thread of criticism set out to change area studies' intellectual shape. After Communism had disappeared from global politics by 1989/1991, theories of global convergence received widespread support, making area studies' concern with regional particularisms appear as "an outdated concern for a world that no longer exists, or at best, that is rapidly fading away" (Szanton, 2004: 24). While the hypothesis of the "End of History" (Fukuyama, 1992) proved wrong, the rising importance of transnationalism did lead to reorientations in the internationally oriented social sciences in another way. Under the conceptual pair global/local, a new paradigm gained ground in which area studies redefined their role within increasingly comparative approaches (Schäfer, 2010). Early examples of this trend have already emerged during the 1980s, when the SSRC established a Committee on the Comparative Study of Muslim Societies in 1986 and launched a new Dissertation Fellowship Program in 1994 favoring cross-area comparative approaches (Szanton, 2004: 26). Recently, Comparative Area Studies has become a widely accepted approach that integrates in-depth case research in a given area in a systematic comparative research design with the aim of generating generalizable theory (Ahram, 2011).

Besides these conceptual considerations, transnationalism has affected area studies in yet another way. The grossly increasing mobility of well-trained scholars from ever more regions of the world has led to far more intense forms of cooperation between Western area scholars and native scholars from the region under study. Additionally, the role of diasporas has been centrally important to area studies. The intimacy of migrant students with their cultures of origin demanded more critical, reflexive, and better grounded teaching than has previously been the offered adding to the quality and a more careful interpretations of foreign cultures (Szanton, 2004: 27).

Areal Linguistics

Lyle Campbell, University of Hawai'i Mānoa, Honolulu, HI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Areal linguistics is defined. A few of the better known linguistic areas of the world are surveyed for the features that characterize them. Issues concerning how areally diffused features are identified, how linguistic areas are established, and what impact areal linguistics has on other aspects of historical linguistics are addressed. Conceptual problems are considered.

Introduction: Defining the Concept

Areal linguistics is about the diffusion of structural features across the languages of a geographical area. The term *linguistic area* refers to a geographical area in which, due to borrowing and language contact, languages of a region have come to share structural features – not just loanwords, but also shared phonological, morphological, syntactic, and other traits. Alternative names sometimes used to refer to a linguistic area are *Sprachbund*, *diffusion area*, *convergence area*, *adstratum*, and *linguistic league*. The key characteristic of a linguistic area is the existence of structural similarities shared among languages of a geographical area, where usually some of the languages are genetically unrelated or at least not all are closely related to one another. It is assumed that the reason the languages of the area share these traits is because they are borrowed.

There have been two approaches to establishing linguistic areas. The more common *circumstantialist* approach lists similarities found in the languages of a geographical area, allowing the list of traits to suggest diffusion, but typically not seeking the specific historical linguistic evidence that could demonstrate that the traits are indeed diffused. The circumstantialist method has been criticized, since it does not eliminate chance, universals, and possibly undetected genetic relationships as alternative possible explanations for the traits shared among the languages. The *historicist* approach seeks concrete evidence showing that the shared traits are diffused. The historicist strategy is preferred because it is more rigorous and reliable, although the lack of clear historical evidence in many cases makes reliance on the circumstantialist approach necessary in many situations.

Linguistic areas are often defined, surprisingly, by a rather small number of shared linguistic traits.

Examples of Linguistic Areas

In what follows, some of the best known linguistic areas are inspected briefly together with the more important of the generally accepted defining traits shared by the languages of each area. A look at these linguistic areas gives a good foundation for understanding some of the issues involving the criteria employed for defining linguistic areas, taken up later below.

The Balkans

The Balkans is the best known linguistic area. The languages of the Balkans area are: Greek, Albanian, Serbo-Croatian, Bulgarian, Macedonian, and Romanian (to which some scholars also add Romani and Turkish). Some salient traits of the Balkans linguistic area are

1. a central vowel/ɨ/(or/ə/) (not present in Greek or Macedonian);
2. syncretism of dative and genitive cases (dative and genitive merged in form and function), illustrated by Romanian *fetei* 'to the girl' or 'girl's,' as in *am data o carte fetei* 'I gave the letter *to the girl*,' and *frate fetei* 'the *girl's* brother';
3. postposed articles (not in Greek), as for example, in Bulgarian *mə^{j}ət* 'the man,' compare *mə^{j}* 'man';
4. periphrastic future (with an auxiliary verb corresponding to 'want' or 'have,' not in Bulgarian or Macedonian), as in Romanian *voi fuma* 'I will smoke' (literally 'I want (to) smoke') and *am a cínta* 'I will sing' (literally 'I have sing');
5. periphrastic perfect (with an auxiliary verb corresponding to 'have');
6. absence of infinitives (rather with constructions equivalent to, for example, 'I want that I go' for 'I want to go');
7. double marking of animate objects by use of a pronoun copy, as in Romanian *i-am scris lui Ion* 'I wrote to John,' literally 'to.him-I wrote him John,' and Greek *ton vlépo ton jáni* 'I see John,' literally 'him.Acc I see him.Acc John.' (Joseph, 1992; Sandfeld, 1930; Schaller, 1975)

South Asia (The Indian Subcontinent)

The South Asian linguistic area is composed of languages belonging to the Indo-Aryan (branch of Indo-European), Dravidian, Munda, and Tibeto-Burman (branch of the Sino-Tibetan) language families. Some traits shared among different languages of the area are

1. retroflex consonants, particularly retroflex stops;
2. absence of prefixes (accept in Munda);
3. presence of a dative-subject construction (that is, dative-experiencer, as in Hindi *mujhe maaluum thaa* 'I knew it' (*mujhe* 'to me' + know + Past));
4. Subject-Object-Verb (SOV) basic word order, including postpositions;
5. absence of a verb 'to have';

6. 'conjunctive or absolutive participles' (tendency for subordinate clauses to have nonfinite verbs, that is, participles, and to be preposed; for example, relative clauses precede the nouns they modify);
7. morphological causatives (causatives signaled by verbal suffixes);
8. so-called 'explicator compound verbs' (where a special auxiliary from a limited set is said to complete the sense of the immediately preceding main verb, and the two verbs together refer to a single event, as for example Hindi *le jaanaa* 'to take (away)' ('take' + 'go'));
9. sound symbolic forms based on reduplication, often with *k* suffixed (for example in Kota, a Dravidian language: *kad-kadk* '(heart) beats fast with guilt or worry'; *a:nk-a:nk* 'to be very strong (of man, bullock), very beautiful (of woman)').

Some of these areal features are not limited to the Indian subcontinent, but can be found also in neighboring languages (for example, SOV basic word order is found throughout much of Eurasia and Northern Africa) and in languages of many other parts of the world. Some of the traits are not necessarily independent of one another, for example, languages with SOV basic word order tend also to have nonfinite (participial) subordinate clauses, especially for relative clauses, and not to have prefixes (Emeneau, 1956, 1980, 2000; Masica, 1976).

Mesoamerica

The language families (including language isolates) which make up the Mesoamerican Linguistic Area are Nahua (branch of Uto-Aztecan), Totonacan, Otomanguean, Mixe-Zoquean, Mayan, Xinkan, Tarascan, Cuitlatec, Tequistlatecan, and Huave. Five areal traits are shared by nearly all Mesoamerican languages, but not by neighboring languages beyond this area, and these are considered particularly diagnostic of the linguistic area:

1. nominal possession of the type *his-dog the man* 'the man's dog,' as in Pipil (Uto-Aztecan): *i-pe:lu ne ta:kat,* literally 'his-dog the man';
2. relational nouns (locative expressions composed of noun roots and possessive pronominal affixes), of the form, for example, *my-head* for 'on me,' as in Tz'utujil (Mayan): (*č-r-i:x* 'behind it, in back of it,' composed of *č-* 'at, in,' *r* 'his/her/its,' and *i:x* 'back,' contrasted with *č-w-i:x* 'behind me,' literally 'at-my-back');
3. vigesimal numeral systems based on combinations of 20, such as that of Chol (Mayan): *hun-k'al* '20' (1 × 20), *ča?-k'al* '40' (2 × 20), *uš-k'al* '60' (3 × 20), *ho?-k'al* '100' (5 × 20), *hun-bahk'* '400' (1-*bahk'*), *ča?-bahk'* '800' (2 × 400), etc.;
4. nonverb-final basic word order (that is, generally no SOV languages) – although Mesoamerica is surrounded by languages both to the north and south which have SOV basic word order, languages within the linguistic area have VOS, VSO, or SVO basic order, not SOV;
5. a number of calques (loan translation compounds) shared by the Mesoamerican languages; these include, for example, 'boa' = 'deer-snake,' 'egg' = 'bird-stone/bone,' 'lime' = 'stone(-ash),' 'knee' = 'leg-head,' and 'wrist' = 'hand-neck.'

Since these five traits are shared almost unanimously throughout Mesoamerican languages but are generally not found in the languages just beyond the borders of Mesoamerica, these traits are considered strong evidence supporting the validity of Mesoamerica as a linguistic area. Four of these five traits have essentially the same distribution, clustering at the borders of Mesoamerica. Such bundling is uncommon in linguistic areas.

A large number of other features are shared among several Mesoamerican languages, but some are not found in all the languages of the area, while others are found also in languages beyond the borders of the area (for details see Campbell et al., 1986).

The Northwest Coast of North America

The Northwest Coast, the best known of linguistic areas in the Americas, includes Tlingit, Eyak, the Athapaskan languages of the region, Haida, Tsimshian, Wakashan, Chimakuan, Salishan, Alsea, Coosan, Kalapuyan, Takelma, and Lower Chinook. These languages are characterized by elaborate systems of consonants, which include series of glottalized stops and affricates, labiovelars, multiple laterals, and uvular stops. There are typically few labial consonant (labials are completely lacking in Tlingit and Tillamook and are quite limited in Eyak and most Athabaskan languages); in contrast, there are several uvular consonants in most of these languages. There are typically few vowels, only three (*i, a, o,* or *i, a, u*) in several of the languages, four in others. Several of the languages have pharyngeals (ħ, ʕ), and most have glottalized resonants and continuants. Shared morphological traits include extensive use of suffixes and the near absence of prefixes; reduplication (of several sorts, signaling iteration, continuative, progressive, plural, collective, distribution, repetition, diminutive, etc.); numeral classifiers; alienable/inalienable oppositions in nouns; evidential markers in verbs; and verbal locative-directional markers; masculine/feminine gender (shown in demonstratives and articles); visibility/invisibility opposition in demonstratives. Aspect is more important than tense. All except Tlingit have passivelike constructions. The negative appears as the first element in a clause regardless of the usual word order. Overt marking of nominal plurals is absent or limited, as in many American Indian languages. Northwest Coast languages also have lexically paired suppletive singular and plural verb stems (that is, a lexical root may be required with a plural subject which is entirely different from the root used with a singular subject).

Some other traits are shared by a smaller number of Northwest Coast languages (see Campbell, 1997: 333–334; cf Sherzer, 1976).

The Baltic

The Baltic linguistic area includes at its core (Balto-)Finnic languages, especially Estonian and Livonian (members of the Finno-Ugric branch of the Uralic family); Baltic languages (Indo-European); and Baltic German (also Indo-European). However, all of the following have been included in different treatments of the Baltic linguistic area: Old Prussian (extinct), Lithuanian, Lavian (Baltic languages, a branch of Indo-European); the 10 Saami (Lapp) languages, Finnish, Estonian, Livonian, Votian, Vepsian, Karelian, and others

(of the (Balto-)Finnic subgroup, a member of the Finno-Ugric branch of the Uralic family); High German, Low German, Baltic German, Yiddish (West Germanic); Danish, Swedish, Norwegian (North Germanic); Russian, Belorussian, Ukranian, Polish, Kashubian (Slavic); Romani (Indo-Aryan); and Karaim (Turkic).

Shared features of the Baltic area include

1. first-syllable stress;
2. palatalization of consonants;
3. tonal contrasts;
4. partitive case/partitive constructions (to signal partially affected objects, equivalent to, for example, 'I ate [some] apple,' in Finnic, Lithuanian, Latvian, Russian, Polish, etc., as for example, in Finnish *söin omena-a* (I.ate apple-PARTITIVE) 'I ate [some] apple');
5. direct objects in the nominative case in a number of constructions which lack overt subjects (Finnic, Baltic, North Russian), as in Finnish *on hyvä syödä omena-Ø* (is good to.eat apple-NOMINATIVE), where it is not possible to substitute *omena-n* (apple-ACCUSATIVE) in this utterance;
6. evidential mood ('John works hard [it is said/reported/inferred]'), in Estonian, Livonian, Latvian, and Lithuanian, as for example in Estonian *ta tege-vat töö-d* (he.NOMINATIVE do-EVIDENTIAL work-PARTITIVE) 'he reportedly is working'/'they say he is working';
7. prepositional verbs (as German *aus-gehen* (out-to.go) 'to go out'), in German, Livonian, Estonian, Baltic, and others;
8. Subject-Verb-Object (SVO) basic word order;
9. agreement of adjectives in number with the nouns which they modify (all languages of the area except Saami languages and Karaim); they also agree in case in all except the Scandinavian languages (which have lost case distinctions for adjectives); they also agree in gender in Baltic, Slavic, Scandinavian, and German, Yiddish, and some others.

For a more complete list of traits attributed to the Baltic linguistic area, see Zeps (1962), Koptjevskaja-Tamm (2002), and especially Koptjevskaja-Tamm and Bernhard Wälchli (2001); cf also Jakobson (1931).

Ethiopia

Languages of the Ethiopian linguistic area include Cushitic (Beja, Awngi, Afar, Sidamo, Somali, etc.), Ethiopian Semitic (Ge'ez, Tigre, Tigrinya, Amharic, etc.), Omotic (Wellamo (Wolaytta), Kefa, Janjero (Yemsa), etc.), Anyuak, Gumuz, and others. Among the traits they share are

1. SOV basic word order, including postpositions;
2. subordinate clause preceding main clause;
3. gerund (nonfinite verb in subordinate clauses, often inflected for person and gender);
4. a 'quoting' construction (a direct quotation followed by some form of 'to say');
5. compound verbs (consisting of a nounlike 'preverb' and a semantically empty auxiliary verb);
6. negative copula;
7. plurals of nouns are not used after numbers;
8. gender distinction in second and third person pronouns;
9. reduplicated intensives;
10. different present tense marker for main and subordinate clauses;
11. the form equivalent to the feminine singular is used for plural concord (feminine singular adjective, verb, or pronoun is used to agree with a plural noun);
12. a singulative construction (the basic nonaffixed noun may be a collective or plural and it requires an affix to make a singular);
13. shared phonological traits such as *f* but no *p*, palatalization, glottalized consonants, gemination, presence of pharyngeal fricatives (ħ and ʕ) (Ferguson, 1976; Thomason, 2001; cf Tosco, 2000).

Several other Linguistic Areas have been proposed, some widely recognized, others with less accepted. These include Amazonia, Ancient Anatolia, Andean Area, Australia, Caucasus, the Cape (Africa), Chaco and the Southern Cone (South America), Central Eurasia, Clear Lake Area (California), Colombian–Central American Area, East Nusantara and Bird's Head (Papua New Guinea), Ecuadoran–Colombian subarea, Ethiopian Highlands, Europe (Standard Average European Area), Great Basin (US), the Guaporé-Mamoré area (South America), the Kalahari Basin, Macro-Sudan Belt, Mainland Southeast Asia, Northeast Area (North America), Northern Asia, Northern California, Northern Northwest Coast (North America), Orinoco-Amazon Area, Plains Area (North America), Plateau Area (North America), Pueblo Area, Qinghai-Ganzu area (China), Sepik River Area (Papua New Guinea), Siberia, South Coast Range (California), Southeast Area (North America), Southern Africa, Southern California and Western Arizona Area, the Tanzanian Rift Valley area, Upper Xingú incipient area (Brazil), the Vaupés (Içana-Vaupés) area (South America), Venezuelan-Antillean Area, among others.

How Are Linguistic Areas Defined?

How linguistic areas are defined has been subject to considerable debate. The following criteria have at times been considered relevant for establishing a linguistic area: (1) the number of traits shared by languages in a geographical area, (2) bundling of the traits in some significant way (for example, clustering at roughly the same geographical boundaries), and (3) the weight or complexity of different areal traits (some accorded more significance for determining areal affiliation on the assumption that it is more difficult for them to be borrowed than others).

The general idea has been that for establishing a linguistic area, the more shared features, the better. Linguistic areas in which many diffused traits are shared among the languages are considered better established. Nevertheless, some scholars believe that even one shared trait may be enough to define a weak linguistic area (Campbell, 1985, 2006). In any event, it is clear that some areas have stronger support than others because their languages share a larger number of traits. In the linguistic areas described above, the number and kind of shared traits vary considerably. Urban (2007) would add 'mutual influence' among the languages to the criteria, which would presumably keep out cases of linguistic areas based on a single diffused trait.

The idea that greater weight should be attributed to some traits than to others for defining a linguistic area can be illustrated with the borrowed word order patterns in the Ethiopian linguistic area. Ethiopian Semitic languages exhibit a number of interconnected word-order patterns that are borrowed from neighboring Cushitic languages. Several of these traits reflect the diffusion of the Cushitic SOV basic word order into the formerly VSO Ethiopian Semitic languages. Typologically the orders Noun-Postposition, Verb-Auxiliary, and Relative Clause-Head Noun are all correlated and tend to co-occur with SOV order cross-linguistically. Their presence in Ethiopian Semitic languages (some of the languages having all of these, others fewer) might seem to reflect several different diffused traits (SOV counted as one, Noun-Postposition as another, and so on), and might be taken as several independent pieces of evidence supporting the linguistic area. However, from the perspective of expected word-order co-occurrences, these word-order arrangements are not independent traits, but reflect the diffusion of a single complex feature, the overall SOV word-order type with its tendency for the various expected coordinated orderings in typologically interrelated constructions to co-occur. However, if borrowed SOV word order is counted as a single diffused areal trait, it may be argued that it should rank high in significance for defining the linguistic area, since it is much more difficult for a language to change so much of its basic structure under areal influence than it is to acquire less complex traits.

Some scholars had thought that the bundling of areal traits, clustering at the boundaries of a linguistic area, might be necessary for defining a linguistic area, though this has proven a poor criterion. Linguistic areas are similar to traditional dialects, where often one trait spreads across more territory than another trait, so that their boundaries (or territories) do not coincide, that is, do not 'bundle.' Typically the geographical extent of individual traits may vary considerably. However, in the rare situation where the areal traits do coincide at a clear boundary, the definition of a linguistic area matching their boundary is relatively secure. As mentioned, several of the traits in the Mesoamerican linguistic area do have the same boundary, though many other traits do not, and typically in other linguistic areas the various areal traits do not share the same geographical boundaries, offering no clearly identifiable outer border of the linguistic areas in question.

Implications of Areal Linguistics for Linguistic Reconstruction and Subgrouping

Areal diffusion can have important implications for comparative reconstruction and for subgrouping within known language families. Nootkan provides a good example which illustrates this. The sound correspondences upon which Nootkan subgrouping is based are given in Table 1.

Table 1 Nootkan sound correspondences

	Makah	Nitinat	Nootka	Proto-Nootkan
1.	b	b	m	*m
2.	b'	b'	m'	m'
3.	d	d	n	*n
4.	d'	d'	n'	*n'
5.	q'	ʕ	ʕ	*q'
6.	Q'^{w}	ʕ	ʕ	*q'^{w}
7.	χ^{w}	χ^{w}	ħ	*χ^{w}
8.	χ	χ	ħ	*χ

Reproduced from Haas, Mary R., 1969. The Prehistory of Languages. Mouton, The Hague.

Nitinat and Makah appear to share the innovation which changed nasals to corresponding voiced stops (in (1)–(4)), while Nitinat and Nootka (Nuu-chah-nulth) appear to share the change of the glottalized uvulars to pharyngeals (in (5) and (6)). Makah and Nitinat also share the retention of uvular fricatives, which Nootka has changed to a pharyngeal (in (7) and (8)); however, shared retentions are not valid evidence for subgrouping. Here, one innovation (denasalization) suggests a subgrouping of Makah-Nitinat together, with Nootka as more distantly related, while the other innovation (pharyngealization) suggests Nitinat-Nootka together, with Makah less closely related. This seeming impasse is solved when we take into account the fact that the absence of nasals is an areal feature shared by several other languages of the area; it diffused into both Makah and Nitinat under areal influence and is thus not real evidence of a shared common development before the languages separated, rather it reached these two languages independently from elsewhere in the linguistic area. The innovation shared by Nitinat and Nootka of glottalized uvulars changing to pharyngeals (in (5) and (6)) is real evidence of subgrouping – a true (nondiffused) shared innovation. So, Nitinat and Nootka together constitute one branch of the family, Makah the other branch. Moreover, with respect to areal implications for reconstruction, if we did not know about the areal diffusion in this case, we might be tempted to reconstruct the voiced stops in Proto-Nootkan, since they occur in more languages than the nasals do, and to postulate a change of these to nasals in Nootka (for (1)–(4)), getting it wrong in this case. Thus, areal linguistic traits can have important implications for classification (subgrouping) and for reconstruction.

Areal Linguistics and Proposals of Distant Genetic Relationship

Similarities among languages that are due to areal diffusion are sometimes mistakenly taken to be evidence of a possible distant genealogical relationship among languages whose classification is in question. The Mosan hypothesis, which proposed a genetic relationship between the Salishan, Wakashan, and Chimakuan language families, illustrates this problem many long-range comparisons have. Several scholars noted structural similarities among languages of these three Northwest Coast language families, but the Mosan hypothesis was not found convincing because much of the evidence turned out to rely on areal traits that are widely borrowed in the Northwest Coast Linguistic Area. Morris Swadesh (1953) presented 16 shared structural similarities in support of Mosan, but most of these are Northwest Coast areal features (some of the traits are also typologically commonplace,

found independently in languages throughout the world), for example:

1. "Extensive use of suffixes."
2. "Nearly complete absence of functioning prefixes in Chimakuan and Wakashan, minor role in comparison to the suffixes in Salish." (Typologically it is not unusual for suffixing languages to lack prefixes.)
3. "Extensive use of stem reduplication, including initial reduplication … and … full stem reduplication."
4. "Aspect, including at least the dichotomy of momentaneous and durative."
5. "Tense is an optional category."
6. "Plural is an optional category."
7. "Dichotomy of non-feminine versus feminine gender shown in demonstratives and articles."
8. "Numeral classifier notions, shown by suffixes."
9. "Two alternate stems for number" (lexically paired distinct singular and plural verb stems).
10. "Lexical suffixes … referring to body parts and other space references."
11. "Predicative use of nouns."
12. "Demonstrative distinctions such as the present versus absent, or visible versus invisible."

As is clear, the traits which Swadesh listed as evidence for the Mosan hypothesis are better explained as the results of diffusion within the Northwest Coast Linguistic Area (see Campbell, 1997 for details).

From this case, it is easy to see why the identification of areal traits is so important in historical linguistics. In this instance, failure to recognize the areal borrowings led to an erroneous proposal of genetic relationship among neighboring language families.

Areal Linguistics and Other Linguistic Concerns

Some implications of areal linguistics for several other areas of linguistics have been addressed in the literature, sometimes only raising new questions, and sometimes helping to provide greater perspective on certain issues. Some of these include linguistic typology, language universals, multilingualism, linguistic prehistory, language ecology, lexical diffusion, dialectology, origins and evolution of language, language classification, diversification and dispersal of the languages, how language changes spread, models of horizontal versus vertical transmission of change, attempted correlations of human genetics and linguistics, explanation and motivation of language change, social interaction (and network theory), discourse, ethnography of communication, etc.

Kinds of 'Linguistic Areas'

It is generally recognized that things that have been called linguistic areas include entities that diverge widely in character and historical backgrounds, depending on marriage patterns, trade, invasion and conquest, prestige, and many sort of social, cultural, political, geographical, and other factors that correlate with diffusion of linguistic features in different regions (Dahl, 2001: 1458; Kuteva, 1998: 308–309; Thomason, 2001: 104). There is discussion in the literature of such different sorts of linguistic areas as incipient areas, only beginning to form and with as yet few shared traits; moribund and decaying areas, where due to many changes after the area was actively formed, fewer traits are currently recognizable among the languages; overlapping areas, where different areas formed on top of or partially overlapping one another at different times for different reasons; multilateral areas (with areal traits spreading from various languages of the region) and unilateral areas (with most traits shared throughout the languages of an area stemming predominantly from one language); areas due to rapid conquest, to population spread and migration (traits moving with movement of speakers), others through home-grown, stay-in-place contact (movement of traits but not of peoples); and disrupted areas with "latecomers, earlier drop-outs, and temporary passers-by" (Stolz, 2002: 265). "In short, the notion 'linguistic area' does not refer a uniform phenomenon, either socially or linguistically" (Thomason, 2001: 115). This array of different kinds of linguistic areas raises questions about whether the concept of 'linguistic area' is justified, whether all these different 'objects' legitimately qualify as 'linguistic areas,' given their very different natures and composition and given the very different circumstances of their birth (and decay). The notion 'linguistic area' offers little upon which these different sorts of linguistic areas can be united other than the fact that they all involve borrowing in some way, but borrowings of different sorts, for different reasons, in different settings, and at different times.

Linguistic Areas versus Borrowing Generally

It is generally acknowledged that linguistic areas are 'notoriously messy,' 'notoriously fuzzy' things (Thomason and Kaufman, 1988: 95; Heine and Kuteva, 2001: 396; Tosco, 2000: 332), and that "what we understand about linguistic areas is depressingly meager" (Thomason, 2001: 99). A common perception is that the term 'linguistic area' is difficult to define (cf Heine and Kuteva, 2001: 409). As Thomason (2001: 99) observes, "linguistics has struggled to define the concept [linguistic area] ever since [Trubetzkoy, 1928], mainly because it isn't always easy to decide whether a particular region constitutes a linguistic area or not." Stolz's (2002: 259) believes "the search for clear-cut definitions [of '*Sprachbund*, linguistics area, and areal type'] has been largely futile and will probably never come to a really satisfying conclusion." In spite of prolonged efforts to define 'linguistic area,' there is no general agreement on its definition, and even for the most widely accepted linguistic areas, such as the Balkans, scholars do not agree wholly on which languages belong to the area, what linguistic traits characterize the area, and what its precise geographical extent is. Campbell (2006) relates this difficulty to the lack of any clear distinction between areal phenomena and borrowing generally. Dahl (2001: 1458) asks

> In the end, we are led to the following more far-going question about the notion of area: to what extent do areas … have a reality of their own and to what extent are they just convenient ways of

summarizing certain phenomena? At the most basic level, linguistic contact relationships are binary: one language influences another. An area is then simply the sum of many such binary relationships.

Campbell (2006) argues that the various definitions of 'linguistic area' offered in the literature confirm that linguistic areas amount to no more than the study of linguistic borrowing in particular languages and its history. Every 'linguistic area,' to the extent that the notion has any meaning at all, arises from an accumulation of individual cases of 'localized diffusion'; it is the investigation of these specific instances of diffusion, and not the pursuit of defining properties for linguistic areas, that increases our understanding and explains the historical facts. With focus rather on specific instances of borrowing, and not on particular matters of geography, many of the unresolved issues and indeterminacies which have dogged areal linguistics from the outset cease to be relevant questions. It is the linguistic changes due to diffusion that count and not the attempt to seek meaning in the geography that secondarily is involved. A linguistic area, to the extent that it may have a legitimate existence at all, is merely the sum of borrowings in individual languages in contact situations. If we focus rather on understanding borrowings, on those historical events, the difficulty of determining what qualifies as a legitimate linguistic area is no longer a problem.

Abstract

Hannah Arendt, American political thinker of German origin, has recently received increasing attention from the academic community as well as from a broader public. This can be attributed to various developments. First, the end of communism, the collapse of the Berlin Wall, and the fading authority of Marxism after 1989 have generated the need for a different understanding of the world. Second, the ongoing debates in Central European countries about the legacy of totalitarianism have rekindled the interest in Arendt's approach to the analysis of totalitarianism. Third, the growing difficulty of Western political systems to integrate various social groups and the upcoming discussion on renewing democracy have given rise to basic questions about how to revive the political sphere. And last but not least, Arendt's concepts of 'freedom' and 'the political' have again given fresh impetus to political theory and to the debate in the political public. Thus, Arendt's way of reflecting the political dimension of democracy fills a void in Western theory and political thinking, which did not arise until after the end of the Cold War. At the same time, her views are increasingly considered in the ongoing debate on establishing democracy in Central and Eastern Europe. Arendt stressed the importance of political thinking and political theory in modern times. She was deeply influenced by the experience of the destructive power in both German National Socialism and Stalinist Communism, but her work cannot be categorized easily. Her notions can be classed within the field of philosophy as well as with historiography and political theory. But she does not object to being described as a political theorist in the sense of public political thinking. Throughout her life she was engaged in political thinking. Feeling the need to meet the intellectual challenge which came up with the self-destruction of European democracies after World War I that led to the strengthening of Stalinism and National Socialism, she published her first famous book *Origins of Totalitarianism* in 1951. Her last work, *The Life of the Mind*, was left unfinished, and was not published until two years after her death in 1975. The objective she pursued was to stimulate a way of human thinking, judging, and acting which orients toward renewing and protecting the political community of the citizen.

Born on 14 October 1906 in Hannover, Arendt grew up in a liberal Jewish family in Koenigsberg. Later, she studied philosophy, protestant theology, and Greek philology in Marburg, Heidelberg, and Freiburg. During this time, she got to know and was greatly influenced by two philosophers: Martin Heidegger and Karl Jaspers. In 1928 she received her Ph.D. in Heidelberg for her thesis on 'The concept of love in the work of St. Augustin.' Understanding the implications of Hitler's accession to power, she left Germany in 1933. She temporarily settled in Paris where she volunteered for a Jewish refugee organization. In 1941 she emigrated to the USA, and became an American citizen 10 years later. She worked as a lecturer at various American universities and colleges, and was a well-known freelance writer who contributed to the American intellectual culture as well as to the postwar European political discourse. Arendt died on 4 December 1975 in New York.

Arendt's Methodological Approach to Theory and Thinking

One cannot comprehend Arendt's thought without taking into account her personal experience of National Socialism and the genocide of the European Jewry. Throughout her life, Arendt always pointed to the existence of National Socialist and Stalinist terror and to concentration camps, which she considered the utmost challenges to political thinking.

It appears that she interlinked all her concepts and categories as well as the history of thought on which she based her notions with the experience of totalitarianism. She considered totalitarianism not only to be a breach in modern civilization but was even convinced that totalitarian rule challenges modern political thinking. This view gave rise to her seemingly unscientific methodological approach to thinking: How to create a world to which mankind feels attached and in which the individual does not lose their ability to judge? How to protect the 'body politic' from self-destruction? In this context, the concept of 'understanding the world' seems to become the overarching hermeneutic idea which interrelates all other categories: judging, acting, being in the public, etc.

Arendt focuses on reconsidering the instruments applied in social sciences. She believes that these were reduced to an absurdity by totalitarianism (see also Lefort, 1988, p. 48). Her considerations encompass a wide range of historical, philosophical, and political references. Her concept of 'the world,' and her radicalization of hermeneutics by questioning the self as a subject have political and philosophical connotations.

There are some specific methodological aspects that need to be considered to understand Arendt's way of thinking:

1. Historically Arendt focuses on the disintegration of the public sphere in the European societies (e.g., France and Germany but also Russia) at the end of the nineteenth century. Her point of reference is the emergence of a new form of total domination in the 1930s, which basically differs from former types of tyranny or dictatorship but refers to the concept of natural law and/or of dialectical law. For Arendt, the need to understand totalitarianism epistemologically arises from the fact that totalitarianism cannot be sufficiently explained by historical and social sciences

(Arendt, 1994, p. 317). She argues that totalitarian rule has had a major impact on the categories applied in social sciences (Arendt, 1994, p. 318). She criticizes social sciences for assuming that political action is basically a rational process (in the sense of Max Weber, *see* Weber, Max (1864–1920)). But totalitarian terror is, in Arendt's view, not at all rational but meaningless and contingent. Therefore, it is not possible to grasp the absolute meaninglessness of destruction, evil, and mass murder by adopting social-science approaches. This is the reason why Arendt's hermeneutic concept is closely interlinked with her criticism of social sciences.

2. Arendt aims to 're-open' the political dimension of modern political thinking by applying her concept of understanding. In this context, 'reopening' means that a dimension, which has been lost, has to be rediscovered: the public sphere as a sphere of human interaction. It is the public sphere that keeps the body politic (the political system) alive. In Arendt's view, the removal of institutions and legal systems as well as the abolition of political freedom under totalitarian rule are direct consequences of the dissolution of the public sphere in modern times.
3. In terms of philosophical categories, understanding is taken to be different from cognition. Understanding is not simply an intellectual concept of the world but is a hermeneutic process, and thus also a philosophical and emotional approach to the world. Understanding is interlinked with experience and judgement.
4. Understanding is also supposed to be different from having 'correct information and knowledge,' although the two are interrelated. Understanding also differs from scientific knowledge. In Arendt's critical view knowledge is meaningless without preliminary understanding. Here, she breaks with the tradition of natural and social sciences according to which the knowledge about facts and details of a phenomenon and putting these pieces together in systematical order means to recognize these facts and details or to realize their truth.

Furthermore, 'understanding' does not mean 'causal and historicist explanation': 'The necessity which all causal historiography consciously or unconsciously presupposes does not exist in history. What really exists is the irrevocability of the events themselves, whose poignant effectiveness in the field of political action does not mean that certain elements of the past have received their final, definite form, but that something inescapably new was born' (Arendt, 1994, p. 326).

In this way, Arendt again draws a line between political thinking and the world of scientific analysis. Her approach denies all teleological and deterministic as well as deductive thinking. However, it includes a fundamental criticism of the concept of progress and rationality in modern history.

Methodologically, her work is challenging insofar as she opposes the traditional (usual) meaning of concepts. In all of her greater works she critically reviews concepts and conceptions as facets of the history of thinking; she eventually tries to re-establish an authentic relation between a given concept, reality and the acting individual; furthermore she seeks to reveal what is new about the object of recognition. Thus, her work is also a major contribution to hermeneutics in social sciences.

Basic Concepts in Arendt's Thinking

Arendt did not evolve a systematic political theory nor did she elaborate a philosophical system. However, her approach to political thinking remains a challenge for both political theory and philosophy. It is based on a different understanding of the major concepts of political theory. Her critical view of the techniques applied in social sciences induced Arendt not only to do research on etymological changes in social science concepts (e.g., freedom, morality) but also to relate her own concept to the overarching idea how to reveal the political dimension in the community of citizens.

The Concept of Society

Society is considered a never-ending process in which citizens act and judge towards an open future within a public sphere; it is not perceived as a set of institutions and ways of living. Arendt opposes traditional views of theory on society by denying that society is to be seen as a (national) entity.

In her view institutions have a protective function. However, they can also pose a threat to the 'humanness of the world.' In this respect, Arendt follows Max Weber in his criticism of bureaucracy. She agrees that the public realm cannot do without institutions, but here again her concept of institution is different, for example, the act of setting up a 'political body' during a revolution is taken to be an institution by itself.

The 'humanness' is supposed to be maintained only by the citizens. Thus, it may not be surprising that Arendt relates her basic concepts to certain abilities of citizens: thinking, judging, and acting in the public realm.

The Political

Arendt's concept of 'the political,' which is basically different from 'politics,' is based on her distinction between the public sphere and the needs and desires dominating the private sphere.

The political is not a substance of humankind but arises in the midst of citizens in the public realm. This is another example of the way in which Arendt relates her concepts to the sphere of interaction. In her view, the political gives rise to a new beginning in the sphere of interaction.

Arendt's way of thinking can be closely related to the tradition of political thinking which emerged in Greek and Roman antiquity. She acknowledged the Greek 'polis' and the Roman republic as historical forms of political sphere, to which die American founding fathers referred to perceiving the republic as a permanent founding of itself (self-instituting) within a system of checks and balances.

Political Freedom

The term 'freedom' (like 'society') refers to a process of interaction in the political sphere and not primarily to institutions. Freedom is not restricted to the individual or to the private sphere. Moreover, 'political freedom is distinct from philosophic freedom in being clearly a quality of the I-can and not of the I-will. Since it is possessed by the citizen rather than by man in general, it can manifest itself only in

communities, where the many who live together have their intercourse both in word and in deed regulated by a great number of *rapports* – laws, customs, habits, and the like. In other words, political freedom is possible only in the sphere of human plurality, and on the premise that this sphere is not simply an extension of the dual I-and-myself to a plural We' (Arendt, 1981a, p. 200).

Basically, political freedom appears to have a double meaning: on the one hand there is the act of setting up a 'political body' (e.g., by means of a constitution) and on the other hand there are the *rapports* of citizens in favor of their political body.

Power

As with the concept of freedom to which it is linked, power is interrelated to the public realm. Arendt does not interlink power with domination, and violence. She disagrees with the definition of power given by major social scientists and especially by Max Weber (Weber, 1978, p. 53).

In Arendt's thinking power, that is, political power, cannot be 'possessed' by individuals nor – as this was assumed during the French Revolution – by 'the people.' On this point Arendt differs from the liberal as well as from the revolutionary concept of power. 'Power corresponds to the human ability, not just to act in concert. Power is never the property of an individual; it belongs to a group and remains in existence only so long as the group keeps together.'

This means that power belongs to the public sphere. It can be incorporated by means of a revolution, a political uprising or an act of founding. However, if power is institutionalized it tends to become bureaucratic. In this respect Arendt agrees with the skepticism of Max Weber about modern bureaucracy.

Thus, power comes up and disappears again depending on the contingency of history.

'Alienation from the World' and 'Being in the World'

Arendt experienced emigration, exile and the deplorable status of a stateless person over many years. It is no accident that the issue of alienation plays a major role in her works. But again, alienation is not related to the private realm but to the public sphere. Alienation refers to the estrangement of individuals from their political community. According to Arendt's theory of humanness, individuals have to 'appear' in the world, join their fellow men and commit themselves to the preservation of the world they live in through their actions. This is what 'citizen' means.

In this context, 'world' (and opposed to 'being without a world'/worldlessness) refers to the fundamental fact of being born into an already existing world.

However, Arendt's concept of alienation differs from the one of Marx or other philosophical authors insofar as it focuses not on the individual but on the relationship between the citizens and the world which they have created (*see* Marx, Karl (1818–83)).

This is the starting point from which Arendt pursues two objectives: to reflect upon how to make the world worldly and to humanize thinking. This is a constant theme throughout her work.

Totalitarianism

All of Arendt's works on political thinking refer to the political events of the time. Her research on totalitarianism during the 1940s focuses on various aspects.

1. She identifies totalitarianism as a new type of total domination. It bases on violent antidemocratic movements which later become part of a political system which engages in the control of institutions and the personal lives of the people, sets up a specific ideology, and establishes systematic terror.
2. She focuses on the 'The origins of totalitarianism,' that is, imperialism and anti-Semitism as the major sources of destroying the political body of the European democracies since the nineteenth century.
3. She considers totalitarianism as representing a breach in modern civilization which began a long time ago. Here again she argues that the categories of thinking are deeply affected by this process.

Arendt considers totalitarian rule as a possible outcome of the weaknesses of modern age. It is bewildering that modern democracies themselves may generate totalitarian elements. Hence, in Arendt's view totalitarian rule cannot be dismissed as an 'accident in history'; there is always the possibility that this form of rule emerges.

This is why it is problematic to discuss moral behavior in a traditional sense after the emergence of totalitarian rule has occurred. Wherever human nature was reduced to the level of 'material' it seems inappropriate to simply re-establish rules that were violated or manipulated. For Arendt, it is important to reflect on the dimensions of a world which gave rise to such a development and which continues to exist after the breakdown of totalitarianism.

Radical and Banal Evil

One word within Arendt's concept of totalitarianism generated major criticism: 'evil.' Arendt distinguishes between radical and banal evil. 'Radical evil' makes human beings superfluous. Arendt uses this concept to find an explanation for Nazi death camps. 'Radical evil' stands for both an absolute and a contingent negation of humanness. The other side of evil is its banality. Arendt takes the Nazi functionary Adolf Eichmann as an example. Her characterization of Eichmann as 'banal' has been widely misinterpreted as a diminution of his personal responsibility (Arendt, 1963). But what Arendt really meant has more to do with another dimension of evil: the absence of thinking (that means, of self-reflection and of conscience). Thus, Arendt presents Eichmann as a specific type of modern person who has lost their relationship to the world as a 'common good.'

Arendt as a Political Thinker of Morality

At first sight it appears strange to describe Arendt's way of thinking as moral (ethical) because Arendt does not evolve a theory of 'acting correctly.' Neither does she construct a system of values. She does not apply moral standards to judge political thinking and acting. Moreover, she deconstructs the

popular meaning of morality by uncovering its etymological roots. It turns out that 'morality' has more to do with being committed to the world than with internalizing values.

Seen from her perspective, acting within the political sphere means to establish civil (civic) manners; this can only be achieved if political action is related to 'home' which may also be called 'the world people share.'

Arendt's principal work 'The origins of totalitarianism' concludes by referring to Heidegger's philosophy. There is a quasi-existential fixed point which is inaccessible to totalitarian rule: the fact of natality. The simple fact that people are born cannot be removed; the birth of a child will continue to represent a new beginning for the world. 'Beginning, before it becomes a historical event, is the supreme capacity of man; politically it is identical with man's freedom… This beginning is guaranteed by each new birth; it is indeed every man' (Arendt, 1981b, p. 479).

Hence the basic prerequisite for human action is there; it is one of the fundamentals of human existence. The question that arises is: How can this existential potentiality of political action be given shape?

Acting politically is only possible in a public sphere. This sphere provides the common world people share in which thinking in public and acting take place. Citizens have to see to it that this public sphere can be renewed. At this point Arendt differs from Kant's theory of morally acting. Unlike Kant, Arendt does not perceive 'polical community' as a limited place, that is, a city (polis) but as a never-ending process of taking action in a sphere that can only be protected by the citizens themselves. The citizens' concerns arise from a joint interest in the world they live in, a world, which keeps on giving new beginning to them.

Arendt considers a renewal of the public sphere to be the only possibility to counteract the (self-)destructive potential of modern times. The conclusion that can be drawn after experiencing totalitarian rule is that evil in the world can only be faced if people commit themselves to making the world they share fit to live in for their fellow citizens and if they permanently renew this 'habitability.'

The difficulty which has arisen is that the distinction between public and private sphere becomes increasingly blurred: it was intentionally destroyed by totalitarian rule, and similarly, it is jeopardized by the increasing importance of social interests and needs in modern society. Nevertheless Arendt argues, a world that is shared by people can only emerge by creating a public sphere. However, this can only be achieved to the extent to which citizens succeed in agreeing on making freedom the overall objective of their actions.

Abstract

Aristocracy as an identifiable element of a social structure has characterized human societies from ancient times, and was more often than not directly associated with land ownership. Different countries developed different forms of aristocracy, sometimes encompassing a small noble class and sometimes an extensive group of farmers on a small or large scale, often labeled the gentry. As a form of government aristocracy was associated with the rule of the wise, and debates about the extent to which this was actually the case, and could be extended and given a social and political role, characterized intellectual life in every society. It was only toward the end of the eighteenth century that aristocracy began to be challenged as a social form, and visions put forward of societies without rank or hierarchy. Although this vision was not brought to reality after the French Revolution (especially after Bonaparte ennobled many of the believers in equality who had survived the revolutionary turmoil), the idea of a society without an aristocratic class continues to attract adherents, combated in turn by those for whom class and social hierarchy are natural social forms.

These three terms embrace the elite groups originally connected with land ownership. They have been used to describe different social types, chiefly in Europe. However, along with 'court,' 'king,' 'prince,' etc., they are also being used to describe diverse tribal (African or Asian) systems of social stratification and power. This article will concentrate on Europe and the Anglophone world with explicative forays to other parts of the world. Much depends upon the language in use. In the British usage, 'nobility' equals 'aristocracy'; the term 'gentry' being used for the landowners without hereditary titles. This does not necessarily fit the continent of Europe, where in early modern times 'the noble' corresponds rather to the English 'squire' than to the 'aristocrat' (Cooper, 1970). All these terms (and their numerous synonyms, like *Ritter*, *Ritterschaft*) have been value-charged, often strongly, but not necessarily and not always positively, such as 'workers aristocracy.' The terms in question change with time: some can be said to be losing their value (including once common terms such as 'Sir' or 'Esq.'). There follow sections on: seclusion of the aristocracy (and/or nobility); interplay of 'immemorial origins,' 'old riches,' and 'royal grace' in the reproduction process of the traditional elites; 'patricians' as an urban aristocracy; *dérogeance* and various patterns of behavior of landed and urban elites; traditional values; inheritance and preservation mechanisms of landed elites; their relations to other estates and classes; the patronage (political and cultural); the royal household; orders of chivalry; growth of the modern state, traditional elites, and state service; and the twilight of the aristocracy in the industrial society, its adaptability to new conditions, aristocratic preserves.

Troublesome Terminology

This article concentrates on Europe. No room can be spared for scrutiny of other parts of the world but one should mention the striking similarities between medieval nobility in Europe and the Japanese *samurai*, as well as in modern times the export of European aristocratic structures to other parts of the world. Even within the European core, diverse terminologies reflected different social structures of particular countries. In the British usage, as noted above, 'nobility' equals 'aristocracy' and was often associated with a peerage; it does not include the wealthy or poor 'gentry' without hereditary title; in France or Poland and across much of Europe, by contrast, the ranks of the gentry would be considered members of a noble class. In this article the term 'nobility' will be used in this comprehensive meaning, corresponding with the German *Adel*, Italian *nobiltà*, or French *noblesse*, all terms originally connected with land ownership. In particular languages there were parallel terms that laid stress on the origins of the nobility. In German *Ritter*, as well as in Swedish *riddare* and French '*chevalier*' or Spanish '*caballero*,' originally signified 'horseman.' In Poland the word *szlachta* stressed its hereditary character (from German *Geschlecht* over Czech *šlechta*), while in Sweden medieval *frälse* underlined their freedom from taxes. All these terms have been widely employed in political argument. They gave birth to various modern descriptive terms like 'workers' 'aristocracy,' or 'trade-union aristocracy.' The derivatives of 'gentry' have in English a particular value, being associated with the improvement of an area (as in 'to be *gentrified*'). In other words, gentrification in English was not synonymous with a process of aristocratization, whereas elsewhere in Europe this might well have been the case.

Ancient-World Origins

The word 'aristocracy' is of ancient Greek origin and signifies the 'rule of the best.' In Homeric times 'the best' signified chiefs of the noble families who pretended to share with the king descent from the gods, and were also prominent because of their wealth and personal prowess. They formed a class of 'horsemen' or 'knights' (*hippeis*) connected by blood and by various community institutions. They governed the state by means of the council of the *gerontes* (the elders). In the eighth and early seventh centuries BC, the social position of the

aristocrats was derived from their land ownership but also could be acquired by commerce, robbery, and piracy. The aristocrats dominated the communities (*poleis*) and organized colonization. Many factors contributed to destruction of aristocratic rule, like change of military tactics (riders in single combat were replaced by *phalanx* of heavily armed foot soldiers) and the ascent of nonagrarian social groups striving for power, and collected in the courts of emperors or in large urban enclaves.

The fate of the aristocracy in ancient Greece followed a pattern that was replicated by many other ruling groups through history: from undisputed moral and political domination to the challenge of rival groups and on to a near-complete loss of power. Prestige related to ancient roots (real or fictitious) survived, however, and would become a constituent element of all aristocracies. Aristocracy as the 'rule of the best' was a moral ideal; if birth was replaced by wealth as the decisive qualification, as tended to happen, the result was oligarchy.

In republican Rome several groups consecutively established an oligarchy of prestige and power. The earliest hereditary estate was that of the patricians (the *patriciate*) who in the late fifth century BC came to dominate almost all of the offices of state. In the later fourth century, their competitors, the plebeians (*plebs*), also began to gain access to power. The outcome was a sort of convergence of the top strata of both estates through matches and family alliances. In the late fourth and the third centuries a new aristocracy began to emerge, the *nobilitas*. Its foundation was the great landed estates run by the slaves and peasants, who were more and more dependent as clients. About 30 houses had access to power both civil and military. The electoral system and honorary unpaid offices secured their domination. Territorial expansion offered them benefits (the fruits of power in the provinces) but at the same time created new dangers. 'The mighty few' (*pauci potentes*, as Cicero called them) were being pressed by the *equites*, originally a moneyed group that in stormy times of civil wars strove for power and was virtually assimilated to the *nobiles*.

Augustus and his imperial successors changed the role of *nobilitas* by the very introduction of the Imperial Court. Later on, along with spatial expansion of the Roman Empire, there emerged provincial aristocracies whose role increased when the center was losing its grip on more distant provinces invaded by the 'Barbarians.' Roman traditions influenced medieval and modern vocabularies of elites.

The Early Middle Ages and La Féodalité

The dissolution of the Roman Empire in the West (fifth century AD) brought about new nobilities from among the retinues of Germanic chieftains and local Roman governors. Their structures were stabilized and let to the emergence of new states. The milieu of princely (royal) households offered opportunities for advancement of diverse social types like the prince's companions, allied tribal chiefs, valiant warriors, and also bondsmen or slaves who had a chance to serve the prince's person directly. A parallel but closely interwoven network was created by the Church. The bishops exercised secular control over large territories, and the Church offered a convenient upward path to able and ambitious persons of modest origin. This is true for later periods as well. When, after the twelfth century, nunneries multiplied, they constituted an opportunities for the daughters of the prominent, who might easily become abbesses or prioresses of great prestige and considerable power. Individual success signified family advancement as well. Close relation to the Church has been for many centuries an important factor in aristocratic modes of life. In Germany even Protestant noble families claimed a right to particular benefices granted by the Catholic Church, which they had traditionally enjoyed before the Reformation.

Medieval and modern aristocracies with their hereditary titles of honor had their roots in the royal household and in the administration of the early state. Office holders strove to obtain permanent hereditary positions. Instability within the early medieval states helped them. In Carolingian times a 'count' (Latin: *comes*) was a judge who accompanied the Emperor. In the twelfth century there emerged other *comites*, provincial governors, and 'viscounts,' who were their representatives. Border provinces of the Empire were governed by the 'marquesses' (German *Markgraf*), 'Duke,' or (German) *Herzog*, which meant 'leader of hosts.' 'Baron' (German *Freiherr*) was either a great landowner or just a substantial 'free man,' i.e., primarily the prince's companion, not his simple subject; it was also an equivalent of 'nobleman.' Accordingly the recipients of the *Magna Carta* (1215) were *barones*.

More rigid rules of interpersonal relationship were conceived originally in France in the twelfth century, and developed into sophisticated structures in subsequent centuries. In that system, now often called 'feudal,' whoever counted was somebody's vassal and had his own vassals as well. Everybody knew his specific rung on a long ladder on top of which was the ruler, who was deemed to enjoy a special relationship with God. This formed a power system based on personal relationships, a skeleton of the medieval 'state,' called by the German constitutional historians *Personenverbandstaat*. Diverse alterations of these rules cannot be analyzed here, although they determined the nature of particular aristocracies. It is enough to mention the notion of 'pairs' or 'peers' (the king's direct vassals equal to each other and also his companions like the legendary 'Knights of the Round Table') making the council of prince's advisors with juridical privileges, and a pressure group conscious of their common interests. In Norman-dominated countries (the most important being England and the Kingdom of Naples) the ruler was recognized as direct *seigneur* of all vassals; in other countries the dominant principle asserted that 'the vassal of my vassal is not my vassal.' The Norman principle became a legal tool whenever the king wished to curb his vassals. In the thirteenth century it helped to create in Naples a bureaucratic state. The other system tended to become a complicated mixture of conflicting loyalties, leading to particular turmoil in France and Germany.

From the late Middle Ages the nobilities in particular countries were shaped by factors as diverse as the intensity of the money economy and customs or laws of inheritance. Money had a destructive influence upon feudal relationships: debts and mortgages haunted landed estates. A system, later called 'bastard feudalism,' replaced the fiefs with monetary payments. In the Hundred Years War the feudal hosts of France proved helpless time and again against English foot militia

employing the longbow. Eventually mercenary troops raised by entrepreneur-commanders replaced them. The most successful commanders aspired to give themselves aristocratic titles. In Italy mercenary commanders (*condottieri*) were nobles, even sovereign princes, and they often recruited their troops among lesser nobles from Romagna, Friuli, or Marche. The nobles were looking for a role within a constantly growing state machine.

Early Modern State: Crisis and Adjustment

Not everybody was seeking to become a nobleman, however. The fifteenth and early sixteenth centuries witnessed multiform crises: rents were falling, and robber knights emerged in Bohemia (they were especially active among the Hussites) and in East Germany. Revolts of lesser nobles broke out in many parts of the Empire: princes and bishops eventually won and razed many knights' castles. In the Renaissance, assemblies of estates, all over Latin Europe, became a source of power parallel to that of the monarch. The nobles participated in them chiefly through a process of election (along with the clergy and the burghers) but the pairs and titled nobles usually had their personal seats secured. The Assemblies became a forum for open competition between the nobility and the burghers. The nobles of a given province usually aimed at a monopoly of posts and offices, against the burghers and any outsiders.

Research in the second half of the twentieth century was particularly concentrated on the 'crises' of the nobility. In most countries the nobles (in the broadest sense) rather successfully adapted themselves to new economic and political conditions but this created major shifts within the estate; hence the 'crisis.' The ideal of an unspoiled and bucolic noble life could be contrasted with that of public service. A precondition for state service was legal training, and the gentry largely disdained formal education. Therefore some rulers encouraged foreign travel or founded special lay colleges (like the Knights' Academy in Siegen or nobles' colleges in Denmark and Sweden). In Elizabethan and Stuart England, young gentlemen crowded into the Inns of Court, and in Scotland the legal training of young noblemen was encouraged in law. In the seventeenth century German nobles embraced a legal training as they needed it in the service of their princes. Not so for the French *noblesse*.

Internal stratification of the estate was of utmost importance to the future of noble ranks. It differed according to size. Here are some estimates: in Denmark, around 1600, the nobles made up 0.25% of population; in Bavaria, Saxony, and Holland slightly more of the population were nobles; in Bohemia and in Prussia, in 1700, 1%; in Poland 7%; and in Castile about 10% (see Labatut, 1978; Meyer, 1973). In some regions (Vizcaya in Spain, Masovia in Poland) membership of the noble estate was far greater.

As states became more centralized rulers took the opportunity to organize their noble subjects into clienteles. 'Liveries' and noble retinues were forbidden in Tudor England and virtually suppressed in Spain in the mid-sixteenth century. In France, a century later, they failed as a weapon of the prince during the *Fronde*. The seventeenth century may be regarded as a century of opposition between the 'Court' and the 'Country.' The former became a principal source of prestige and privilege, a center of culture and power. It was never as important in England, at least after the Tudors, as it was in France, Spain, and Austria.

In the East, where demesne farming prevailed, the state was 'coercion-intensive' (as Charles Tilly, 1990 has termed it). In Prussia and Livonia, the landed gentry (*Junkers*) identified with the state and its army. In Russia, they were the Tsar's dependent servants and did not become an estate before the mid-eighteenth century. In Poland a sequence of fifteenth-century statutes secured independence from the royal administration. The structure of politics in Poland–Lithuania was shaped by the relationship between the gentry and the landed magnates. Neither of these groups was interested in a strong executive, after an elective monarchy was introduced, and the political patronage of the magnates became the dominant factor in the politics of the state.

In Sweden, nobility, having virtually no medieval traditions, developed into an estate of civil and military officers through the ennoblement of commoners. Absolutist reforms in 1680 then challenged the aristocracy and diminished its authority. The system of ranks (known also in Denmark and later introduced into Russia) served the interests of the monarch. In France, the *noblesse d'epée* felt endangered by the robins (*noblesse de robe*), or newcomers, who were buying land and titles of nobility on a large scale. Strict *dérogeance*, a ban on improper and disqualifying sources of income, such as trade, created economic problems. The high aristocracy had enjoyed military commands and governorships of provinces as their *chasse gardée*. But their influence was rather restricted to the Court and its intrigues, masterfully described in the memoirs of Duke de Saint-Simon (1699–1752).

Pride and Prejudice

One may argue that noble culture has been based on these two vices. The whole idea of nobility drew from tradition, and much imagination was employed to deepen the roots of each family tree. The Renaissance discovery of Roman literature enriched noble imagination with hosts of ancient heroes. Most seminal were the escapees from burning Troy. When in 1624 a scion of the distinguished Lithuanian family Pac visited Florence, both he and his hosts, the Pazzi, were happy to get 'proof' of their common heroic, Homeric origins. The nobilities favored imagined glorious ancestry: the Germanic Francs (as opposed to the commoners descending from the Celtic Gauls) in France, and in England the Norman knights of William the Conqueror. The Lithuanian gentry descended from a Palemon (from Troy) and the Polish one from Japhet son of Noah (as contrasted with Cham for the peasantry and Sem for the Jews). In Italy, France, and Spain noblemen and scholars discussed the relative importance of long and impeccable pedigree, which were seen to be the basis of a noble lifestyle and accompanying traits such as personal valor.

Of more practical importance to the maintenance of noble classes were property rights and the laws governing inheritance. These determined the economic continuity of families. Chiefly in the south (Naples, the Islands, Spain) feudal property was dominant, which in cases of conflict, became a tool of the monarch. In the England of the early Stuarts, the Court of

Wards was an instrument of fiscal oppression of the nobles and the Long Parliament abolished it in 1640. In Naples and Sicily the nobles continuously pressed their Spanish sovereigns for more liberal rules concerning feudal inheritance.

The preferred rule of inheritance was the entail, which treated landed estates as family property and neutralized the tendency to division. However, it limited opportunities to mortgage the real estate and left open the fates of younger sons and daughters. In the English case, entail served landed property well: it kept property intact and the younger sons easily found jobs in business, the professions, royal service, and eventually in the colonies. On the Continent, ambitious, less substantial nobles as 'noblemen-errant' searched for service abroad. Count Achatius zu Dohna (from Prussia) and Prince Eugene (of Savoy) were among the best known. In Poland, shared inheritance contributed to the impoverishment of the gentry and the growth of wealthy magnates. The latter secured entail, for themselves alone, as a legal exemption.

Urban Aristocracies

The cities had aristocracies of their own. North of the Alps, they were usually called the 'patriciate' and in Italy simply *nobiltà*. In the High Middle Ages, before town guilds took over the government, most cities were run by royal officers of noble extraction. The most impressive relics of that early stage and its lifestyle are 13 towers that dominate the cityscape of San Gimignano and the incredible constructions still towering over Bologna. In most cities, however (Florence and Basle for example) victorious town guilds destroyed these bastions of noble power, only to create new elites of their own. The large, wealthy town offered great benefits to the people of influence, and led to strong oligarchic trends in urban 'communes.' The top families were often more aristocratic than the aristocrats *sensu strictiori*. In Italy and later also in south Germany, ruling elites introduced the *serrata*, or closed lists of families with exclusive right to city offices in a given city. The most famous was the Golden Book of Venice (1297) but it was by no means unique. The patricians cultivated their special ways and observed *dérogeance* taboos. In Germany, the symbol of urban independence was 'Roland,' the legendary companion of Charlemagne and personification of knightly valor. King Arthur too became the eponym of exclusive clubs (*Artushöfe*). The urban patricians built country residences and acquired landed property chiefly as a status symbol. It was often apparent that they treated this as a collective enterprise. In the fifteenth and sixteenth centuries, in the Swiss city of Luzern, a small cluster of patrician families raised urban troops and leased them to neighboring powers. The patricians commanded them and collected most of the money paid for their services. Profits from power and politics were closely interwoven.

The *connubium* or marriage market strictly limited to elite families created problems, and between the sixteenth and eighteenth centuries many urban aristocracies from Venice to Lübeck experienced a shortage of skilled candidates for urban offices. The medieval register of noble families, centuries later, did not secure wealth compatible with their social standing. Therefore the Venetian *nobiltà* created, at the city's expense, a system of social welfare for the noble poor.

In general, the urban patriciate in many respects was similar to the aristocracy. They were closely related too, naturally enough, because landed aristocrats did not scorn urban money. In Germany, patricians from many cities of the Empire (*Reichsstädte*) enjoyed the status of the *Reichsadel*. The Habsburgs granted aristocratic titles to wealthy burghers who supported them with loans and banking services. Names like Fugger (Augsburg), Doria, and Spinola (Genoa) are only the most famous among many. In some cases the patrician was automatically regarded as a noble: in the tiny imperial city (*Reichsstadt*) of Wels, owners of important local salt (brine) wells were, by imperial patent, regarded as nobles (incidentally, this status was enjoyed by Franz von Papen, who preceded Hitler as German Chancellor). In France some city posts were ennobled almost automatically. Even the most exclusive Maltese Order excepted candidates from Florence, Genoa, Lucca, and Pisa from its very strict *dérogeance* rules.

Members of the urban elite merged with the nobility *tout court* in many ways. They met at Royal Councils, acquired landed estates and prestigious titles, and profited from the inflation of honors in the sixteenth and seventeenth centuries. They defended their exclusive status against the bureaucratic encroachments of enlightened autocrats. The elites of some larger cities made a particularly closed, self-conscious caste. The twilight of the patrician civilization was best described by Thomas Mann in *Buddenbrooks* (1901).

Triumph and Twilight of Aristocracy

The French Revolution closed a chapter, but not the whole story, of European aristocracy. Although aristocrats were given preference onto the scaffold (even an heiress of Tchernobyl, who visited Paris at the wrong time, lost her head), the First Consul and later Emperor Napoleon Bonaparte created his own Court and constituted a new stratum of *notables* based on loyalty to the ruler. Political changes largely destroyed the prestige of French élites whose membership reflected, in the nineteenth century, the vicissitudes of the nation. But still, in 1839, the Marquess Astolphe de Custine argued that the true nobility cannot be bestowed or purchased. The ruler, he continued, can appoint dukes; education, opportunity, and genius or virtue can create heroes; but nobody and nothing can make a noble. Yet everywhere commoners were being ennobled: bankers, industrial entrepreneurs, statesmen and politicians, army and navy officers, across the states of Europe. Monarchies, even restricted by the constitutions of the second half of the nineteenth century, needed traditional elites as political support and as an ornament. In Berlin, the last emperor Wilhelm II recreated a very formal and lavish court ceremonial. In Britain, in 1876 Queen Victoria became Empress of India and made Benjamin Disraeli, a statesman of Jewish extraction, Earl of Beaconsfield. Immemorial traditions were being cheerfully reinvented. In Britain, the 'first industrial state,' the high nobility had a greater share of land than in other states and continued to enjoy substantial political influence.

By contrast, in the East, after the dissolution of the Polish Republic (1795) the three partitioning powers inherited numerous lesser nobles but almost no titled ones. This unusual gap had to be filled and eventually anybody who was able to

prove membership of the Senate among his ancestors, and who pursued a noble lifestyle, could become baron or count. 'Austrian Count' became, in Poland, an ironic comment. In general, however, in the monarchies, ennoblement and aristocratic titles were becoming a mere ornament and a final prize for distinguished service and/or business performance.

Constitutional and political changes in Europe in 1917–18 and after were destructive of the nobility, and not only those in Europe. Neither republican Spain nor Franco's Spain were supportive of traditional Spanish aristocracies, either at home or in the colonies of Latin America.

After 1918 radical projects for agrarian reforms threatened noble power in many countries but it was entirely destroyed only in the Soviet Russia. The former Russian aristocrat who became a taxi driver in Paris became a literary *topos*. Another totalitarian system, Nazi Germany, was supported by the Prussian Junkers. In the beginning, Adolf Hitler's party seemed to them too radical, too plebeian, but the preceding Weimar Republic had also been disappointing for them. Nevertheless the Junkers turned to Hitler because they shared nationalistic commitments and a fear of the left. At the same time, as the war went badly, many aristocrats were prominent within the internal opposition.

Perhaps the *Credo* of the late aristocrats eventually challenging the Nazi dictator could have been outlined that way: the aristocracy never collaborates with the tyrant in defense of order; its tradition is on the one hand the defense of the people against despotism, and on the other the defense of civilization against revolution, that most dreadful of tyrants (or so Astolphe de Custine had had it). The failed coup against Hitler on 20 July 1944 brought the lives of many aristocratic Prussians to a bloody end, and the postwar loss to Poland of the territories beyond Oder-Neisse frontier cut off their economic base.

The conspiracy against Hitler was perhaps the last conscious political action of an aristocracy. The political influence of that class seemed lost for good, notwithstanding the distinguished intellectual, scientific, or political performance of their individual members. What remains is the value of their collective tradition and the sentiment or flavor so well presented to the modern world by a *Principe* Giuseppe Tomaso di Lampedusa or a Jean Marquis d'Ormesson. Having said this, it may well be the case that neoliberal economic reforms are paving the way for the establishment of a new global aristocracy of bankers and hedge-fund managers, owners of land and owners of scarce natural resources, and owners of new technology companies. A corporate elite, equally, is emerging, many members of which have strong personal and private links to the politicians whom they serve through the outsourcing of public services, including defense. Whether these trends will lead to new forms of aristocratic living is an open question.

Armed Conflict and Social Work: Significance and Implications

Shulamit Ramon, Anglia Ruskin University, Cambridge, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

An underresearched area, this article is aimed at understanding the complexity of the impact of armed conflict on individuals and communities in the context of social work. For this purpose, key definitions, the scale of those affected by the phenomenon, and its impact are considered. Issues related to researching armed conflict are highlighted. The relevance of social work support during different facets of armed conflict follows, including the dilemmas that this type of intervention raises for social workers. Throughout the text, the international character of armed conflict is emphasized, and examples are given from different parts of the world.

Introduction

Making sense of the significance and implications of armed conflict for social work requires clarity about what constitutes armed conflict. Armed conflict is a political conflict in which arms are used to attack the other side, defined as 'the enemy,' and to defend one's own side. Although this is the definition of war, the concept of war is usually kept for an armed conflict between two or more countries, while the term 'civil war' is used to describe a war within one nation or country.

Armed conflict is not a useful term for describing hostilities between two groups in which arms are not applied, but which are nevertheless powerful, and may be either the outcome of an armed conflict, or lead to one in the future. Most conflicts between ethnic minorities and majorities, coexisting religions, and travelers and nontravelers do not result in armed conflict most of the time, but may plant the seed for such a conflict in the future. The war in the then Yugoslavia in the 1990s provides a good example of a political conflict that simmered for 50 years before it erupted into outright war. This article considers the relevance of social work support during different facets of armed conflict, including the dilemmas that intervening poses for social workers. It emphasizes the international character of armed conflict, giving examples from different parts of the world.

Contextualized Background Information

There are 15.3 million refugees of war from 21 countries, according to the United Nations (UN) Higher Commissioner for Refugees (UNHCR, 2012). Refugees are people who have left their own country due to a violent conflict and 10.5 million of them are looked after by the UNHCR, while 4.8 million of these are looked after by the UN Refugees Welfare Agency in the Middle East refugee camps based in Jordan, Lebanon, and the Palestinian Authority (PA) where they have been since 1949.

Twenty-seven million people are recognized as internally displaced people (IDP). They live mainly in their country of origin, but away from where they lived when the conflict began, which they left due to the impact of an ongoing internal war (civil war) or occupation by another country. This brings the total number of refugees and IDP to 42 million, likely to be an underestimate, because many of those leaving in a hurry in the chaotic situation of an armed conflict, are often not counted and do not declare themselves as either IDP or refugees.

Asylum seekers are people who declare themselves as refugees, live outside their country, and whose status has not been confirmed as refugees by the authorities in the country in which they reside. The total number of asylum seekers is not known, as not every country releases this information, and also because some of them enter a country illegally, or without the knowledge of the authorities. Recent information from the UNHCR (2012) states that in 2012, there were 108 912 asylum seekers in industrialized countries, a rise of 25% from the 2009 to 2010 figures.

Their treatment in the host countries and country of origin should follow the Geneva Convention (established in 1951). It should also follow the UN Convention and Protocol (1967) on the status of refugees, endorsed by the UN, although not signed by all countries (see Ramon and Magljlic, 2012). In reality, this is not always the case, especially for IDP or asylum seekers, where each country decides how they should be treated.

Experiencing Armed Conflict

Some of the most negative outcomes of armed conflict appear daily on television screens. Losses of many types characterize the impact of armed conflict, such as loss of life, limbs, family members and friends, animals, property, or items of sentimental value. The loss of the sense of security and of future prospects for many of the survivors of an armed conflict may take a very long time to heal, and in many instances remain unhealed and potentially lead to further conflict in future.

Economic devastation is often a direct outcome of an armed conflict, in which the means of production have been destroyed, leading to supply shortages of food, water, and means of construction. The lack of food and shelter leads to an increased rate of illness and death among the more vulnerable population groups, such as children, women, and old people (Watchlist, 2003 (Web site); ECHO, 2013 (Web site); Doucet and Denov, 2012; Krill, 2000).

The destruction of medical facilities and the disappearance of health personnel lead to a high rate of disability and increased mortality among those wounded. The long-term

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28007-0

physical, psychological, and social impact on those affected has been documented (e.g., Doucet and Denov, 2012). These include the long-term impact on women, Beah's (2007) personal account of being forced to be a child soldier, and Nuttman-Shwartz et al.'s (2011) account of the long-term impact of posttraumatic stress disorder (PTSD).

Long-Term Impact

Most of the current ongoing armed conflicts, across all continents, have their roots in the past history of the communities engaged in them. For instance, the current Syrian conflict has its roots in the history of the relationships between the Alawite minority groups and the Sunni majority; the aftermath of the war in Iraq is marked by the renewed conflict between the Sunni and the Shia communities, which has also been at the background of the war between Iraq and Iran in the 1980s.

It is the interpretation of the past, and what is remembered of it by those who witnessed the conflict and subsequent generations who reinterpret the past in the light of the present, that counts and makes the differences between looking for another round of armed conflict or its prevention. Memories are always constructed, although often individual memories are suppressed in favor of memories perceived by those in power as suitable for collective consumption (Halbwachs, 1992).

Social work practitioners need to be aware of these issues in their work with individuals and communities, to enable individuals to resolve their memories that conflict with the collective injunction. For example, in Bosnia, Moslem women experiencing rape in the 1990s were not allowed to mention this experience due to the wish to repress the assumed guilt of their menfolk in being unable to prevent the rape (Zavirsek, 2008: p. 162).

Considerable efforts have gone into collectively remembering some conflicts, such as the Second World War, the Holocaust of Jews and Gypsies in Europe, and beyond these groups at that time, or in subsequent events of a similar nature. Moreover, some other conflicts, no less horrendous or far reaching, are not equally collectively commemorated, e.g., the Armenian genocide and the Biafra war.

The wish to remember, and for such events to be etched into the collective memory, is understandable in the light of the magnitude of what has happened (Zavirsek, 2008). Furthermore, where the underlying reasons for the conflict have not been resolved, and where people continue to lead an uprooted life, it is likely that the conflict will resurface, as is the case in the Middle East, where a third generation of those who left Palestine in 1948 live in refugee camps, do not have full citizen rights in the countries where the camps are located, live on UNWRA financial support, have poor future prospects, and are highly unlikely to return to the land of Palestine–Israel, a country they have never been to, but which has acquired a mythical significance for them, as it did for Jews for over 2000 years.

At the individual level, there is a range beginning with people who wish not to forget any element of the conflict, ending in those who wish to forget all of it, with people who have nightmares connected to it to those for whom it does not matter in the middle. PTSD is a recognized psychiatric diagnosis, attributed to people suffering from reliving selected situations of the conflict and finding it difficult to continue with their ordinary life (Nuttman-Shwartz et al., 2011).

Enabling to share significant memories both collectively and individually is an important part of community social work/development work in rebuilding a community impacted by armed conflict, helping to cement community cohesiveness. Yet, carrying out this work without rekindling the wish for revenge and reliving traumatic events presents a challenge to social workers.

Positive Outcomes of Armed Conflict

Side by side with the high level of mindless brutality that war unleashes, a kinder human approach during armed conflicts and their aftermath can be observed. Positive outcomes include in-group and outer-group solidarity; instances of human generosity; readiness to risk one's own life for the sake of the lives of others; tireless work toward conflict resolution and peace building; health and social reforms that would not have taken place without being stimulated by the wish that something positive will come out of such negative events; and creative art (see L'Art en Guerre, 2013).

Specific examples include Anna Freud and Dorothy Burlingham (who was a social worker) revising their psychoanalytically oriented work with children following the lessons learned from their involvement in the experience of mass evacuation of British children during the Second World War (Freud and Burlingham, 1943). This has led to more caution in considering moving children from home when a parent becomes ill and unable to look after them, to much greater focus on the family as a unit during family consultation services (Felsman, 2001). The recognition that many of the behaviors displayed by the evacuated children were normal reactions to abnormal situations helped to reduce the detection of pathology, and diagnosis of these children as suffering from forms of mental illness.

When Sarajevo's psychiatric hospital was bombed out of existence during the Bosnian war, the option of not to rebuild it was accepted, enabling the more radical change of the mental health system there to proceed and move it from being a heavily institutionalized and segregating system to one with a number of community services (Kucukalic et al., 2005).

The value of an individual acting courageously to raise awareness and encourage international organizations to take the necessary steps has been exemplified by Malala Yousafzia recently. Aged 14 years, she was shot in the SWAT Valley of Pakistan in October 2012 by the Taliban because she protested against their policy of excluding girls from schooling in Pakistan. The shooting was not only condemned internationally, but also resulted in expressed mass solidarity with her in Pakistan and elsewhere (Amnesty International Newsletter, November 2012: pp. 10–17). She has survived the shooting, but had to pay the price of emigrating from her country to the United Kingdom. Malala has continued her activities for girls' education, and has received during 2013 the International Peace Prize for Youth.

Researching Armed Conflict

Research into armed conflict is needed to achieve better conceptual understandings, give meaning to people's experiences of it, and develop strategies for preventing the next round of armed conflict and the harm to the population from the ensuing outcomes. Yet, carrying out methodologically sound research is not an easy task. There is potential physical risk to researchers and those participating in the research during an acute conflict stage. Risk is also heightened because such research touches on highly sensitive and emotionally charged issues.

Researchers of human behavior are likely to use qualitative methods that encompass their own values and biases (Lincoln and Guba, 1985). This may introduce a lack of 'objectivity' that becomes multiplied in armed conflicts, when sympathy with one side provides the credentials that enable the researcher who is asking for permission to carry out research to do so. Furthermore, the sensitivity of the themes requiring research is difficult to encompass through simple methodology and methods, while researching in harsh conditions calls for simplicity.

Although impartiality is unattainable, commitment to uphold universal ethical rules and reflect on one's own biases go some way to ensure that this research is carried out ethically (Kelly, 2004). Two types of research can be identified: research aimed at better understanding the context and stakeholders' positions and evaluation of policies and interventions, including social work interventions.

Despite these difficulties, examples of sound research in relation to values and methodology exist, some of which are outlined below. Miljenovic and Zganec (2012) researched the views of local residents in a region of Croatia that showed signs of community disintegration after the 1990s war there. They developed a framework of the factors of community life that mattered to the residents, and interviewed key people representing these elements. Deteriorating economic development topped the list, followed by dysfunctional social relations between the ethnic groups that were leading a separate coexistence, difficulties in the way public institutions were functioning, and crisis of local government. Meanwhile, international nongovernmental organizations (NGOs) were active, but internal NGOs were operating in an uncoordinated fashion that lacked continuity. On the basis of this research, the authors proposed how community building could proceed.

A survey of 10 countries across Africa, Asia, Europe, and South America, undertaken recently by the World Health Organization (Fisher et al., 2011), highlights the difficulties that adolescents face in war situations. In total, 4868 adolescents from armed conflict areas participated in these studies, and although they come from different contexts, the similarities in the findings are striking. The findings include high exposure to traumatic events, high to severe levels of PTSD symptoms, varied therapeutic responses, and the impact of the context on the severity of difficulties experienced and adequacy of responses. For example, those who became child soldiers had not only experienced traumatic events, but also scored much higher than the clinical cutoff point on depression and PTSD scales. Much needed evaluation of policy implementation is provided in a recent study of UNCHR community empowerment projects in Sierra Leone (Skran, 2012).

Only a small number of studies looked at the impact of armed conflict on social workers (e.g., Campbell and McCrystal, 2005; Ramon et al., 2006; Baum and Ramon, 2010), although this group is highly likely to be impacted by armed conflicts. Al Mikhamresh et al. (2012), researching social work activities with Iraqi refugees in Jordan, highlight the need for politically competent social work practice, in the sense of having to understand well the 'political map' in the situation and use this understanding to benefit clients. Guru (2012) refers to the dilemma of the researcher attempting to work with families of young Moslem men accused of engaging in terrorist activities. This research sympathizes with the families and wishes to understand better their context, but is not sure how ethical it is to research such families at the crisis stage in which their lives are embedded, while the researchers simultaneously experience difficulties in getting ethical permission to carry out this research on the grounds of potential risk to them.

The Relevance of Social Work to the Humanitarian Activities Undertaken in Armed Conflict Contexts

Local social workers in an armed conflict context are usually part of the workforce providing different types of support, working alongside doctors and administrators, and local and international organizations. At the time of an acute conflict, they will provide any help they can – food, shelter, accompanying people to medical services, taking children left without parents to a safer place, and sharing in their grief.

Support at the postacute stage may differ. At times, this focuses on economic support, including rebuilding local enterprises, emotional support in the form of formal and informal counseling, bereavement work, referring survivors to disability services, reconnecting people, supporting people to go back to their original geographic or ancestral location, and enabling memory work to take place (Zavirsek, 2008). The social work response needs to be tailored to the variations in the reactions to the traumas experienced during an armed conflict in a given population. Focus on community and group work is often more effective than individual work in increasing solidarity and mutual support. Good practice examples range from Northern Ireland to South Africa (O'Brien, 2003) to the development of advocacy practice centers in Israel, Jordan, and Palestine (Moshe-Gorodofsky, 2012), and memory work with three generations in Chile (Zavirsek, 2008). Doucet and Denov (2012) describe the work of social workers in Sierra Leone with women returnees from the civil war. In this, the clients were engaged in agricultural work alongside their social workers, in a situation in which these women were excommunicated by their own community and the social workers too had to find additional source of subsistence to their meager salary (Doucet and Denov, 2012).

Lindsay (2008) describes the work carried out by Palestinian school social workers who work with school children, their parents, and teachers when children are arrested, or who have to spend hours at checkpoints just to get to their workplace. Israeli social workers outlined what it meant to provide group mediation and emotional support to settlers evacuated from the Gaza strip, despite their vocal objection to this move (Nuttman-Shwartz, 2008).

Being local is an advantage in terms of knowing what is available and how to behave, an essential element of offering emotional and social support. Yet, being local can be a disadvantage when a civil war is raging, as it will be assumed that the social worker would side with the position taken by her or his national/tribal group, and hence defined as either part of 'us' or of 'the enemy,' and treated as such. Wairire (2008) describes such a situation in Kenya, where social workers try to mediate between tribes engaged in war on territory and cattle, and may risk their lives as a result. Working for international humanitarian agencies often entails carrying out social work activities, such as rapid assessment, responding to the need for immediate relief to a traumatic war event, and distributing food, medicine, and shelter. At the postconflict stage, the complexity to be confronted is even more demanding, including displaced people with little to do, buy, or sell, and worried about the people left behind, sick, or disabled.

Maglijlic-Holicek and Rasidagic (2008) have looked at the role of international NGOs in Bosnia-Herzogovina during the armed conflict there in the 1990s and its aftermath. Being a major tool in the application of the Dayton Peace Agreement, alongside the UN Peace Corps, they brought a new language, one of Western policy terms, and favored people who spoke English regardless of their other qualities or lack of them, over local people with the qualities and experience required for welfare work. The usual pitfalls in understanding local conditions, power games, and the diversified needs of the local population, played an additional role in making these overseas workers ineffective in their activities.

The Impact of Armed Conflict on Social Workers

Social workers participate in armed conflicts as both citizens and professionals. Like any other citizen, they too, experience increased physical and psychological vulnerability during the conflict. Yet, being citizens makes them more sensitive to the plight of specific groups, and alert to dangers that their loved ones may be facing while they are working as professionals. They may be committed to one of the two sides in the conflict.

As professionals, their mandate is similar to that of doctors – namely, to support their clients, and those people who become their clients during the armed conflict, regardless of the political affiliation of the latter. Working during a conflict may be difficult, in terms of physical danger, in being exposed to more acute losses and suffering than is normally the case (e.g., being the bearer of bad news to families), lacking necessary resources, or having to provide services to people whose views they object to. They may at times feel that they have to provide an example to others who are more vulnerable than they are (e.g., Palestinian school counselors, as described by Lindsay, 2008) or rise to the challenges that the conflict has provided and with that an opportunity to acquire a higher level of skills while highlighting to the general public the centrality of the social work contribution (Ramon, 2004; Baum and Ramon, 2010). For some social workers, the solutions adopted included deflecting the political nature of their work (e.g., mental health social workers in Belfast, as described by Campbell and McCrystal (2005)).

This context inevitably contains ethical dilemmas, which social workers may or may not be aware of. Cemlyn (2008) and Cemlyn and Nye (2012), looking at working with asylum seekers and travelers in England, indicate a range of such dilemmas resulting from the misfit of English legislation and policy and social work values. A minority of social workers are also engaged politically in campaigning for the values they believe in. Doing so from a platform of social work values is challenging, as highlighted in Moshe-Gorodofsky and Yudelevich's (2012) recent Israeli example.

Training and Educational Initiatives

Training and education offer the possibility of preparing service providers to offer targeted service for vulnerable groups caught in armed conflict. The trainers must be responsive to local conditions and sensitivities. For example, Moshe-Gorodofsky (2012) reports on a program aimed at preparing community advocates in Israel, Jordan, and Palestine as volunteers who respond to citizens experiencing the negative outcomes of armed conflict. The program enables the advocates to meet with their counterparts from the three countries in a neutral location, a once in a lifetime opportunity to meet the enemy as human beings who share values and ways of working with each other. Butler (2005) has led a fieldwork placement on a social work degree in Plymouth, in which students worked as social work trainees with refugees. Using a community development and welfare rights approach, this enabled students to have a much better understanding of the issues faced by refugees, develop empathy and demonstrate it, and try to resolve individual issues within the limitations imposed in the UK system on what refugees can and cannot do. This placement enabled students to test their adherence to the values taught on the degree course, and acquire the necessary knowledge and skills for this type of work.

Lindsay (2008) developed a training program for school counselors in the PA in Ramallah with local educators. This project enabled a 2-year training program for people from a variety of different disciplinary backgrounds to acquire knowledge and skills of providing a social work service to children and their teachers in an area where daily confrontation took place with Israeli soldiers and settlers. As the children were also engaged in protest activities against the occupation, and the workers were experiencing frequent difficulties in getting to the workplace through the roadblocks manned by the Israeli army, the newly qualified workers had to grapple with the issues that working under these complex conditions raised.

Examples of encountering obstacles related to the armed conflict and attempting to overcome them include a period of not being paid salaries due to the temporary withdrawal of EU funding because of an escalation of the political conflict in 2007. This affected directly the participants in the training who were in many cases the sole bread winners of their families. They considered taking strike action, but decided against it because of the importance of the training to them (Lindsay, 2008: pp. 233–234). Many of the participants were often stopped at border crossing by the Israeli army and it took them a long time to get to work, but put up with this obstacle as an example to the children they were working with

to strive toward a normal, nonviolent life as much as possible (Lindsay, 2008).

These examples raise the question of what input is needed within the basic qualification for social workers and in post-qualifying programs on armed conflicts. This question is particularly pertinent given the universal lack of attention to this issue in most well-established social work programs, despite attempts to encourage engaging with it (Duffy et al., 2013). The main reason usually given for this blatant lack is the already burdened curriculum, which is a polite way of saying that this issue is perceived as being of lesser importance than those already in the curriculum, and constitutes a denial of the significance of armed and political conflicts to an ever increasing number of countries across the globe.

The few existing initiatives are located in countries that are in a postacute armed conflict stage or have become more acutely aware of the impact of a long simmering conflict. An example of an initiative developed in the peace-building phase is provided by the school of social work at Queens University Belfast, Northern Ireland (Duffy, 2006; Campbell and Duffy, 2008). Service users who have experienced the impact of this conflict (locally known as 'The Troubles') were invited to address social work students in their introduction to the social work course. The invitation was to a local voluntary sector organization that works with families affected by 'The Troubles.' A well worked-out protocol was developed relating to the aims of this initiative, how to approach the students over the several seminars that were focused on this issue, what to tell or not tell about oneself, preparing the students who come increasingly from the two sides of the conflict, and how to evaluate the outcomes. This has been a successful initiative to judge by students' and presenters' comments (Duffy, 2006). However, social workers who have been affected in this conflict both as citizens and as professionals have not been invited to address the students thus far.

Conclusion

This article has highlighted the complexity of the issues entailed in social workers' understanding of and responses to the needs of populations experiencing armed conflict and included the impact of such conflicts on social workers themselves. The text covered research evidence, and the need for further research was also identified.

The insufficient attention paid to the impact of armed conflict in social work, and in social work education, and good practice examples were identified. Given that armed conflicts are part of the reality of the twenty-first century, it is hoped that the social work profession, its researchers, and educators will move from paying lip service to this crucial issue to give it the centrality it deserves. Likewise, there is a place for multidisciplinary work between social workers and other relevant disciplines to occur soon. In the context of armed conflict, social work knowledge takes key concepts concerning trauma, displacement, rebuilding communities, and research methods from psychology and sociology in particular. Practitioners work closely with varied health practitioners and educators and planners.

Epidemiologists, economists, and system managers also play an important role in different stages of an armed conflict. In meeting other disciplines on this issue, the role of social workers is both to inform and be informed, to decide which of the contributions of the other disciplines is of particular relevance to social work, as well as whether and how it fits social work values. An interesting example is provided by Dan Bar-On in his seminal article on the silence of psychologists as a discipline when faced with armed conflict (Bar-On, 2001). He argues that in this case, the allegiance to science, perceived as objective and beyond biases, prevents psychologists from taking a moral stand as well as a knowledge-building one. This article helps to understand similar positions taken by social workers, social work researchers, and social work educators, and understand how such a reaction does not fit the values that social work stands for, because these include social workers' defense of human rights. Compared to other social sciences disciplines, social workers' activities in armed conflict situations, and the research led by social work researchers on this issue, are far less known outside the discipline, calling for more effort to be put into wider dissemination of existing understandings of the issues entailed and evidence accumulated within social work.

Arms Control

Abstract

The article begins by defining the term and distinguishing between 'arms control' and 'disarmament' in both theory and practice. The analysis continues with a review of the negotiating history, with particular reference to US–Soviet efforts to delimit the bilateral nuclear competition from the mid-1960s to the early 1990s. The third section focuses on the disruption to and the broadening of the arms control agenda occasioned by the collapse of the Soviet Union in 1991 and the spread of nuclear weapons and ballistic-missile technologies (i.e., the problem of 'horizontal proliferation') to second- and third-tier states. The article concludes with a detailed look at the enduring tension in arms control and nuclear strategy between efforts to prevent the outbreak of war through the codification of nuclear deterrence and the renewed interest in national (and theater) missile defense as the preferred approach to the maintenance of national and international security.

Arms control, a term popularized in the early 1960s, may be defined as the effort, between and among countries, to negotiate binding limitations on the number and types of armaments or armed forces, on their deployment and disposition, or on the use of particular types of armaments. It also includes measures designed to reduce the danger of accidental nuclear war and to alleviate concerns about surprise attack. Although the two terms are often used interchangeably, it is distinct from disarmament, which has the more ambitious objective of seeking to eliminate, also by international agreement, the means by which countries wage war (Blacker and Duffy, 1984). The goal of eliminating war extends far back in history, but in modern times disarmament came into focus with the Hague Peace Conferences in 1899 and 1907. These and subsequent efforts met with what can only be termed limited success.

Schelling and Halperin, in their seminal work, *Strategy and Arms Control*, first published in 1961, listed three objectives for arms control: to reduce the likelihood of war; to limit the extent of damage should war occur; and to reduce expenditures on military forces. As US and Soviet weapons arsenals mushroomed during the Cold War and each country spent liberally to keep pace with the other militarily, later analysts tended to offer less sweeping goals. These included reducing the number of nuclear weapons and redirecting the arms race into areas less likely to threaten the stability of the international system.

The end of the Cold War and the collapse of the Soviet Union gave rise to expectations, both at the expert level and among publics more broadly, that the sudden cessation of the superpower arms race would create opportunities for radical reductions in the nuclear and conventional weapons arsenals of the major powers.

Although the leading industrialized countries have taken some steps in that direction – US armed forces, measured in terms of total numbers, have declined by one-third since 1990 – progress in eliminating the nuclear-weapons stockpiles of the US and Russia has proven to be an elusive goal. To compound the problem, the number of nuclear-armed states has actually grown in recent years as India and Pakistan, in a series of highly publicized weapons tests in 1998, announced their arrival as full-fledged nuclear powers. The means to deliver these weapons, as well as chemical and biological agents, across hundreds (and even thousands) of miles has also spread as countries such as North Korea, Iraq, and Iran continue to invest heavily in programs to develop and deploy long-range ballistic missiles.

Arms control, particularly between the US and the Soviet Union, aroused controversy from the outset. The Limited Test Ban Treaty, signed by representatives of the US, the United Kingdom, and the Soviet Union in 1963, provoked sharp debate when US president John F. Kennedy submitted this arms control 'first' for Senate approval. Some critics saw the treaty, which prohibits the testing of nuclear weapons above ground, under water, and in space, as unenforceable. These and other concerns notwithstanding, the treaty eventually was ratified and fears of Soviet noncompliance proved to be unfounded.

More favorably received in the US was the United Nations-sponsored Nuclear Non-Proliferation Treaty (NPT), which sought to restrict the size of the 'nuclear club' by inducing non-nuclear weapons states to renounce the acquisition of such weapons in exchange for a commitment (among other pledges) on the part of the nuclear-weapons countries to reduce their own arsenals. The NPT, which entered into force in 1970, was renegotiated in 1995, at which time the signatory states agreed to extend the treaty's provisions for an unlimited period of time. Conspicuous by their absence as states-parties to the NPT are the two newest declared nuclear powers, India and Pakistan, as well as Israel, which is believed to possess a small but sophisticated arsenal of nuclear weapons.

The NPT was critically important in facilitating the start of bilateral US–Soviet negotiations in 1969 to limit central strategic forces. Known by the acronym SALT, for Strategic Arms Limitation Talks, the negotiations resulted in two arms-control agreements in 1972. The first and more important was the Antiballistic Missile (ABM) Treaty, by which the two countries agreed to limit the number of ABM sites and thus not deploy nationwide defensive systems to protect their homelands against nuclear-missile attack. The second accord was a 5-year freeze on the construction of long-range land- and sea-based ballistic missile 'launchers' (underground silos and submarine missile tubes, respectively). The so-called Interim Agreement on Offensive Weapons was a temporary measure to slow

the competition in offensive weaponry, pending negotiation of a more permanent and restrictive treaty (Newhouse, 1973).

The second phase of the negotiations, lasting from 1972 to 1979, led to the signing of several agreements, including an accord further limiting US and Soviet ABM deployments and the 1974 Threshold Test Ban Treaty, which restricts the yields of underground nuclear weapons tests. The most important agreement concluded during this period was the 1979 SALT II treaty, a lengthy and complex document that attempted to extend and refine many of the provisions of the 1972 Interim Agreement (Talbott, 1979). The US Senate never ratified the treaty, however, largely because of the dramatic deterioration in superpower relations that began during the abbreviated administration of President Gerald Ford and accelerated during the term of his White House successor, Jimmy Carter. Despite the ambiguous legal status of the treaty following the failure to obtain its ratification, both the US and the Soviet Union abided by most of its provisions well into the 1980s.

Negotiations on US and Soviet strategic nuclear forces, renamed the Strategic Arms Reduction Talks (START) by President Ronald Reagan, resumed in the summer of 1982. Through the remainder of Reagan's presidency, the two sides reached consensus on many key points, including the desirability of 50% reductions in long-range nuclear forces and the need for intrusive, on-site inspections to prevent cheating.

Among the issues not resolved was how to construct the preferred relationship between strategic offensive and defensive forces. In a dramatic reversal of its earlier negotiating position, the US now favored the rapid development and deployment of nationwide defensive systems, as shown by its sponsorship of the Strategic Defense Initiative (SDI), first outlined by Reagan in March 1983 in a nationally televised address (Fitzgerald, 2000; Nolan, 1989). The Soviet Union was sharply critical of SDI and resisted the conclusion of any new agreement to reduce strategic offensive weapons, pending a commitment by the US to abide by the terms of the ABM treaty, narrowly interpreted, through at least the end of the century.

The rise to power of the Soviet leader Mikhail Gorbachev in 1985 signaled a fundamentally new phase in arms control. One of Gorbachev's most important foreign policy objectives was to curtail sharply the political rivalry between the USSR and the West by, among other steps, delimiting their military competition. The first major result of this policy was the Intermediate-Range Nuclear Forces (INF) Treaty, concluded in 1987, which eliminated all US and Soviet land-based nuclear missiles with ranges between 500 and 5500 kilometers. This was followed in 1990 by a treaty to reduce conventional forces in Europe (CFE), signed by 22 member-states of the North Atlantic Treaty Organization (NATO) and the now-defunct Warsaw Pact. At about the same time, US and Soviet negotiators completed work on the long-awaited START treaty, and in July 1991, President George Bush traveled to Moscow to join Gorbachev in signing the accord. Less than 6 months later, Gorbachev – the architect of the most ambitious reform program in the 74 year history of the Soviet Union – resigned as president and the USSR ceased to exist.

At a hastily called summit meeting in June 1992, Bush and Russian Federation president Boris Yeltsin agreed to press for early ratification of the START treaty. They also pledged to conclude a second and more ambitious agreement to reduce US and Russian strategic nuclear arsenals by up to two-thirds within a decade and to eliminate all multiple-warhead land-based missiles. Some 2 weeks before the inauguration of Bill Clinton as US president in January 1993, the two sides made good on their promise and concluded the START II treaty. As relations between the US and Russia deteriorated during the second half of the 1990s, the treaty itself languished; although finally ratified by both sides, nearly a decade after its signing most of the agreement's provisions still had not been implemented.

The US–Russian arms-control agenda has also been complicated by the confused, and confusing, nuclear legacy of the Soviet Union. In the wake of the Soviet collapse, four of the country's now independent republics, including Russia, found themselves in possession of thousands of nuclear weapons and hundreds of long-range delivery systems. Under pressure from Russia and the West, in May 1992 the governments of Belarus, Kazakhstan, and Ukraine promised to abide by the terms of the 1991 START I agreement and to join the NPT as non-nuclear weapons states. With financial and technical assistance from the US, all nuclear warheads and their associated missile systems deployed on Belarusian, Kazakh, and Ukrainian territory eventually were disarmed and dismantled. The denuclearization of the three former Soviet republics constitutes the most important – and perhaps the only unambiguous – arms control success story of the 1990s.

The abrupt end of Soviet rule gave rise to a second kind of security problem for which policymakers everywhere were ill prepared. The frequency and intensity of ethnically and religiously inspired conflicts in such heretofore remote parts of the former USSR as Tajikistan and the southern Caucasus increased dramatically following the collapse of central authority in Moscow. The breakdown of political control in these and proximate regions, coupled with the extreme poverty that afflicted many of the people caught in the fighting, served both to prolong these struggles and to frustrate diplomatic efforts to contain them.

In addition, the unraveling of the Soviet Union's alliance relationships left a number of countries politically orphaned and therefore less secure. This too served to increase regional instability. It also encouraged some states – North Korea being a case in point – to seek to develop nuclear weapons of their own despite the determined opposition of the major powers, especially the US.

At the start of the twenty-first century the most important challenge to arms control, however, is the prospective change in the relationship between long-range, offensive nuclear forces and weapons designed to defend against them. For the last 40 years, what Philip Green characterized in the mid-1960s as the deadly logic of nuclear deterrence helped preserve the uneasy truce between Washington and Moscow. In its simplest form, deterrence held that no rational leadership in possession of nuclear weapons would ever intentionally authorize their use against a nuclear-armed adversary because of the near-certain knowledge that the victim of such an attack would retaliate in kind. With effectively no ability to ward off or deflect such a retaliatory strike, the would-be aggressor would thus be deterred from initiating a nuclear exchange in the first place (Brodie, 1965; Schelling, 1960).

As the capacity to build nuclear weapons spreads to countries other than the so-called great powers, interest in acquiring the means to defend against their possible use has grown, particularly in the US. Even a comparatively modest system of active defenses – one designed to defeat a handful of incoming ballistic missile warheads launched from whatever quarter – arouses concern, however, because of the latent ability of such a system to expand and improve over time. The larger and more robust a system of national missile defense becomes, the better it will be at defending against more complex threats. The more able it becomes, in other words, the more threatening it will seem to the more established nuclear powers, including Russia and China, for whom the unchallenged ability to retaliate with overwhelming force constitutes the bedrock of their security (Wilkening, 2000). According to the classic tenets of arms control, the large-scale deployment of strategic defensive systems could therefore erode stability and increase the likelihood of war.

It is probably not beyond human ingenuity to design and construct a 'mixed' strategic environment that allows for a modicum of defense while preserving nuclear deterrence in its essentials. Given the understandable urge to escape the persistent threat of nuclear annihilation, it seems safe to assume that governments will persist in their efforts to square this strategic circle. Policymakers everywhere would do well to remember, however, that nuclear deterrence, for all its flaws, has kept the peace for half a century, and that any attempt to replace it with something else is likely to entail serious risks and potentially enormous costs.

Editor's Note

Dr Blacker's recounting of arms control leaves off near the end of the 1990s and only hints at the arms control issues that would plague the world in the ensuing years, specifically, how to keep weapons of mass destruction out of the hands of non-state actors, terrorist organizations, splinter 'states' and other potentially dangerous groups. For a comprehensive update covering all this and more, see Williams and Viotti, 2012.

Abstract

Raymond Aron was too respectful of each person's freedom to found a school of thought. But his mark in French political history and thinking is just as profound due to the fact that, far from relying on a network of disciples and institutions, it is anchored in an intellectual heritage that transcends partisan differences or academic studies. Aron succeeded in continuing and revitalizing, in the midst of the century of ideologies, the tradition of French political liberalism. More than that, he was the academic teacher and the intellectual who defended the *primacy of politics* in an era dominated by social sciences and economy. The rebirth of the political thinking in France in the 1980s is his legacy. In France, his attitude and his writings – particularly the publication of *L'Opium des Intellectuels* (1955) – contributed decisively in progressively detaching the intellectuals from antiliberal regimes and, from there, to the resistance of French society to antiliberal regimes. At the same time, Aron's action and thinking were of tremendous importance in the conversion of a large part of governmental and administrative elite to the Atlantic Alliance and the building of the European Community. Abroad, he acquired a huge moral notoriety and had a privileged relationship with numerous scholars, philosophers, and statesmen, such as Henry Kissinger with whom he maintained a frequent dialogue. Aron thus is a unique example of a twentieth-century French intellectual who was both patriot and European, republican and liberal, antitotalitarian and cosmopolitan. In the face of collective passions and demagogy, which overtake regularly democracies in general and French political life in particular, Aron played the major part, according to Claude Lévi-Strauss of a 'teacher of intellectual hygiene.'

Biographical Elements

Raymond Aron was born on 14 March 1905 in Paris. His family originated from Lorraine, a territory partly attached to the German Empire at the moment. His father was a professor of law. In 1924, he enters the *École Normale Supérieur* (ENS), the most prestigious public institution of higher education, along with Paul Nizan and Jean-Paul Sartre. All three were intellectuals, philosophers, and editorialists with great influence on public opinion on major political issues. He succeeded in his philosophy aggregation concourse in 1928, and in 1930, he taught as a lecturer at the University of Köln, and right after at the Academic House of Berlin from 1931 to 1933. These years in Germany and Berlin would shape the intellectual choices of the young philosopher, and would orientate him toward German Sociology, especially Max Weber, giving him a fleur of the tumultuous twentieth-century politics that was about to transform Europe. Back to France, he taught at the College of Le Havre (1933–34), and then occupied the post of secretary of the *Social Documentation Centre* in the ENS till 1939. In 1938, he publicly defended his major thesis, *An Introduction to the Philosophy of History* and his minor one, *The Critical Philosophy of History*. This second work along with *Contemporary German Sociology* (Aron, 1935) was the first presentation of great German philosophers and sociologists, like Dilthey, Tönnies, Weber, Simmel, and Tröelsch in France.

In 1939, he was drafted and fought the Nazi Germany in what was known as the *drôle de guerre* that led to the occupation of France. By the end of June 1939, he embarked for London, where he joined General De Gaulle and the Free French Forces, whose emblem was Larraine's Cross. In London, he became chief of the editorial board of the journal *La France Libre*. After the liberation, he continued his public interventions. In 1945, he founded avec Jean-Paul Sartre la revue cosmopolite *Les Temps modernes*, and collaborated with Albert Camus in the *Combat* (1945–46). He worked as an editorialist at the *Figaro* (1947–77), and the *Express* (1977–83). Thus, he participated actively in the political and ideological debates of his times. He would defend political and economical liberalism and liberal values in a public space obsessed by ideas about socialism and communist revolution. His opposition to Sartre and the communist camp is legendary and incarnated in the intellectual mode of the 1960s: "better be wrong with Sartre than right with Aron." His opposition would culminate in his major work on *The Opium of the Intellectuals* (1955), where he denounces a self-blinded left intelligentsia bringing to light its erroneous ideological framework. For more than 40 years, he analyzed international and interior politics, strategies, diplomacies, and conjectures, and established himself as one of the best analysts of the Cold War era.

From 1945 to 1978, he occupied a number of prestigious positions in the French academic system: professor at the *Institute of Political Studies* in Paris (1945–54) and the *National School of Administration* (1945–47), professor holding the chair of sociology in the Faculty of Letters of Paris-Sorbonne University (1955–67), Director of the 6th section of the *École Pratique des Hautes Études* (1960–78), which would become the *École des Hautes Études en Sciences Sociales*, Professor at the *Collège de France* (chair of sociology of modern civilization, 1970–78). During these years, he contributed to the creation of a number of political philosophical reviews like *Commentaire*, *Preuves*, *Contre-point*, which formed the ideas of liberal political thinking and philosophy in France.

One of the great voices of his time, he had a particular pathos for dialogue and open mindedness, that made him an eminent interlocutor of philosophers with conflicting ideologies, like Cornelius Castoriadis and Leo Strauss. He has formed a great number of philosophers and political thinkers like

Pierre Manent and Jean-Claude Casanova, who he then sent to Chicago to conclude their studies under the direction of Leo Strauss, Jean Bæchler, Alain Besançon, and influenced the works of thinkers like Kostas Papaïonnou, Cornelius Castoriadis, Julien Freund, André Glucksmann, and Pierre Hassner. Raymond Aron died in Paris on 17 October 1983, a little after the publication of his *Mémoires*, which was an immediate success. French politician and major European political actor, Jacques Delors described him as "one of the greatest intellectuals of our time," and the anthropologist Claude Lévi-Strauss as "our last sage."

Works

Aron has left behind him a polyvalent and multi-axis work. He was an acute observer of social reality and contemporary history. He undertook studies on philosophy of history, on sociology and sociological theory, on political theory and ideology, on war and international relations. He wrote major works on liberty, ideology and totalitarianism, economy, class and industrial society, Cold War politics, war theory and diplomacy in an open dialogue with Marx, Weber, Pareto, Tocqueville, and Clausewitz, with a constant orientation to the actual and present time conjunctures and interests.

On Philosophy of History

Influenced by the German school of sociology, Aron's work on philosophy of history focuses on the historical condition of the social researcher and theoretical knowledge of our societies. In his *Introduction to the Philosophy of History*: *An Essay on the Limits of Historical Objectivity* (Aron, 1938), Aron enters in a dialogue between Hegelian heritage and Weber's critique of Hegel's philosophy. He distinguishes between 'objective spirit' and 'objectivated spirit.' If 'objective spirit' is a quasi-metaphysical entity, 'objectivated spirit' is a part of everyday life and understanding. Aron takes the example of a bell in the chambers of a bourgeois apartment. He argues that in order to understand the use and function of this object, we have to understand the logic of class society, the distinction between masters and servants: the master calls using the ring, and the servant answers the call obeying to the wishes of his master. This interaction implies of course the logic of salary work and moneyed interest. The argument is based on the fact that historical interpretation must be based in a reconstruction of a theatrical scene that will ultimately reveal the nature of the object in question. Historical knowledge is thus contextualized, and the limits of historical interpretation are the limits of our imagination to figure out contextualized situations. In this sense, there is no unique interpretation of historical events, as the process of historical understanding implies an open dialogue between the present state of the researcher and his ability to project to past time experiences. The very meaning of historical experience and experience of the past is constantly varying regarding to the everyday experience in and of the present. In other words, both Hegel's theory of the possibility of an objective knowledge and Weber's intuition of the distinction between values and facts are put here in difficulty. Facts are value permeable, and values can be understood as facts, that is, they can be 'objectivated,' in the process of historical understanding. Furthermore, the very idea of an 'objective' knowledge of our present experiences can only be understood as a sum of social interactions in which the social researcher is both social actor and historical judge. This does not, however, invalidate any historical knowledge: it just emphasizes on the fact that there is no ultimate interpretation and understanding of history, but only a perpetual dialogue and even conflict between social scientists.

But can such a knowledge be pertinent for practical action? In *Politics and History* (Aron, 1978), Aron gives an example, using Thucydides' historical narrative as to how ancient history, or our understanding of it, can be useful for political actors in the twentieth century. He argues that despite of the social and economical complexity of modern day societies, Thucydides' narrative sheds some light in basic political interactions, as war and war-based diplomacy. Similarities between fifth century BC Athens and twentieth century AD Cold War experience can only be understood if we consider the basic human structures of war and politics. Facts such as alliances and power diplomacy, dilemmas such as justice and the use of force remain intact as an anthropological basis to the understanding of human societies how complex may they become. In other words, and as far as power confrontation is concerned, Thucydides' experience is as good as ours. History, as Aron understands it, that is as a "skeptical intellectual shaped by the experience of fascism and World War II" understands it, leaves little doubt as to the inevitable preeminence of politics and war in human societies. Historical synthesis of human progress by explaining events to come in the light of human creativity and accomplishments only tells one side of the story. Eventually, we will come to Aristotle's conclusion that human events are of probabilistic and not of deterministic nature, and such is the nature of their narratives and understandings of them.

Aron believed in the utility of historical research combined to philosophical dialogue with the great thinkers of the past. Difficult and fundamental concepts, such as power and liberty, shaped in the past can help us forge our future: political decisions can hardly be taken without the experience and skillful interferences with such concepts and philosophical understandings. As history interferes with politics, it becomes clear to Aron that present and past historical events can only be understood in terms of a complex of variables to be determined and examined alongside the comparison of political experiences and philosophies in different historical and social contexts. This is actually the meaning and the sense of a comparison between Machiavelli and Marx, or between Tocqueville and Marx on liberal society: to define the fundamental concepts of power and liberty that influence our political action. Without this historical knowledge, modern era's computer-based war games are blind.

On Sociology and Sociological Theory

Raymond Aron is mostly known in the academic world as a sociologist. He held the chair of Sociology at the Paris-Sorbonne University (1955–67) and later a chair of sociology in the *College of France* (1970–78), a most prestigious advanced studies research institution in Paris. In 1967, he published *Les Étapes de la pensée sociologique* (Aron, 1967, 1968c), a book that

would determine the mainstream sociological thinkers in France for the years to come. Aron counts between the fathers of sociological thinking Comte, Marx, Pareto, Durkheim, and Weber, and also Montesquieu and Tocqueville. Regrettably, he did not include Georg Simmel, although he was the first to present him to the French public as an historian. An "intellectual gallery of portraits," this book is a consecration of the founding fathers of sociology. In the first part of the book, Aron distinguishes three schools: (1) The French school of political sociology, following Montesquieu and Tocqueville, a non-dogmatic school mostly interested in politics but who did not ignore social infrastructure. Aron includes himself in this school. (2) The school of Auguste Comte that leads through Durkheim to contemporary French sociology. This school minimizes the role of politics and economy emphasizing in the social aspect of unity through consensus. (3) The Marxist school. The Marxist theory, explains Aron, exists in two versions: a doctrine of the State leading the believers in a classless society fantasy, and a subtle one, destined to be understood only by intelligent people. According to this theory, the socioeconomical structures and the historical process can explain society, as a whole. The latter leads necessarily to the final triumph of socialism. The second part of this book presents Pareto, Durkheim, and Weber. All three, comments Aron, belong to the generation *tournant de siècle*, who lived in a relative social stability, but shared a pessimistic sentiment of Europe in crisis. All three, notes Aron, felt that the withdrawal of religion caused by the rise of modern science and technology left societies without moral guidance. They believed that social science could, in a certain extent, contribute to the restoration of social morality, but despite this belief, they understood well that societal values were beyond the rational grasp of science.

Aron often described himself as a *Marxian* but not as a Marxist, rejecting Marxism's poetical enthusiasm and embracing Marx's scientific and analytical prose. In 1962, Aron pronounced his courses on *Marx's Marxism* in the Sorbonne, and repeats the same seminars in the *Collège de France* in the 1970s. Jean-Claude Casanova, publisher of *Le Marxisme de Marx* (Aron, 2002), notes the very words of Aron in his inaugural course: "Today, it has been 30 years that I have been studying Marx." Although he confesses his inability to become a Marxist, Aron acknowledges that Marx was his initiator on social philosophy. Aron hopes to establish that Marx's critical power resides not in the concept of alienation, as the young Marxists of his time believed, but in his critique of religion, law, and economy. Aron refuses to accept that the Marx of the *Manuscripts of 1844* should shadow his mature work. Alienation was a concept of the young Marx that did not last long. Marx's genius consists in questioning not only social reality but also our own conscience of reality. Beginning by a critique of religion, he continues with the critique of Law, and arrives naturally in the critique of political economy. The critique of religion is also the critique of the illusions of religion and in the same time the critique of the society that was produced by these illusions. This kind of reasoning can be transposed in economy. Economists think that profit comes from the earth or the capital, but this is an illusion: it comes from the exploitation of workers. Economical actors live in a false world, and cannot realize it because they refuse to recognize themselves for what they are. This blindness of all classes, proletarians and bourgeois, even of economists is what allows the system to work. For Aron, the *Capital* is an 'economico-philosophical' book that combines German philosophy and English political economy. Aron himself went through the same exercise: write a philosophical book in an economical language.

In the same year 1962 when he commenced his seminars on Marx, Aron published *Eighteen Courses on Industrial Society* (Aron, 1962a), courses taught in the Sorbonne during 1955 and 1956. In this work he notes that industrial societies are based on the idea of progress, and that productivity means above all progress in science, technology, and evolution of means. A strong growth needs perpetual transformations of industry and production, which leads to social and political transformations. He then examines the growth of Soviet industry and understands that quantitative industrial growth is not accompanied by positive qualitative change of citizen's living but rather to forced population displacement from the countryside to the industrial areas with a much lower standard of living. This is according to Aron the sign of the Soviet failure to provide a better way of life. Finally, he argues that the capitalist system leads to democracy – the market, syndicates, and consumers are counterpowers – better standards of living, and deceleration of growth. His previsions of 1955 both came true less than 50 years later, when Soviet economy collapsed and capitalist economy is decelerating.

On Political Theory and Ideology

Aron belongs to the French School of political sociology and follows the works and methods of Montesquieu and Tocqueville. He analyses together liberal democracy and its enemies, totalitarian regimes (Aron, 1965). Modern societies, he argues, tend by their very nature to equality, a lesson taught by both Montesquieu and Alexis de Tocqueville. In this longing for even more equality, two perspectives are open for modern societies: either relative equality through democratic reforms, which would lead to a pluralist constitutional regime, or absolute equality through revolution, and the imposition of a monopolistic party regime. Aron insists on the conflictual and pluralist character of liberal democracies, as he opposes two types of regime: a constitutional-pluralist one and another of a monopolistic party. This opposition actually recovers a series of oppositions: political and economical concurrence or monopole, constitution or revolution, social pluralism or absolutism, party State or partisan State (Audier, 2004). Respect of legalism and the sense for compromise (Aron, 1965) is the principle of the constitutional-pluralist regime, argues Aron. It is what is denied in the monopolistic party regime. Such a regime would come to extinction if it were corrupted by the democratic sense of compromise. Instead, absolutism is its strength, and its principle is the sentiment of fear and faith. Militants' faith and non-militant's fear is the force and capacity for action for totalitarian regimes as dialogue and open-minded conflict is for liberal pluralist ones. Of course, Aron argues, there are many variations of one or multiple party regimes and even mixed forms, like monopolistic regimes introducing a Constitution and respecting individual rights or pluralistic regimes presenting an oligarchic character. And then again, liberal regimes are also open to corruption.

It was the special historical circumstances of the academic year 1957–58, when Aron offered the seminars on *Democracy and Totalitarianism* (Aron, 1965) that pushed his reflection on the corruption of constitutional-pluralist regimes. As Aron states in his introduction, "a legal savior inherited a corrupted Republic." The passage from the 4th to the 5th French Republic, and the end of the Algerian War, which ended with the independence of Algeria, gave Aron a critical insight into the liberal pluralistic regimes. There are three major types of corruption that can endanger liberal constitutional regimes claims Aron. The first appears when the party system does not any more correspond to the various groups of interests or when no stable authority can come out of the rivalry between parties. The second is the corruption of the public spirit, or the corruption of the *principle*, as Montesquieu would have called it. Either the partisan spirit of the parties' militants is too strong and erases any notion of common good, or the spirit of compromise is too strong and there can be no decision making. Last, corruption could come of the failure of the social infrastructure, if class conflicts are too intense and the political system of the parties is incapable of withholding them within limits. Excessive oligarchy or excessive demagogy can lead to social dissolution and political decay. Aron notes that corruption of liberal regimes is either due to not much time in power, which means that the political system is fresh and does not have yet deep roots into society, or too much time in power, and a long period of decomposition. A corrupted regime, concludes Aron, can continue existing for a long period of time, as revolution is not necessarily what follows. But it can also, under specific conditions, like the Republic of Weimar in Germany in 1933, crumble into totalitarianism.

Aron defines the totalitarian regimes as a mixture of ideological frenzy and police terror. In addition, totalitarian regimes center on a controlled economy based on State planning. In the case of the Soviet regime, Aron makes some interesting remarks. First, that there have been free elections after the takeover in 1917. This first Parliament was of course dissolved, as it did not serve the Bolsheviks. Second, that there have been many Constitutions over the years. And third, that there was a separation between the State and the party, even if only for diplomatic reasons. As the party proclaims liberation by revolution, and the State has to negotiate and develop diplomatic relations with Western capitalistic forces, it would be difficult for the State to bear openly the party's ideology. This shows according to Aron that if Hitler and the fascist regimes show open hostility to democratic principles, the communist regime embraces them, even if it does not apply them. One of the forces of the communist totalitarianism is that it proclaims his faith in the principles it fights against. This is a 'passionate problem,' notes Aron. The answer to this apparent contradiction lies in the distance between the ideological 'truth' and the social and economical reality. The very organization of the party and the State are by ideological definition transient, suspended on the destruction of class society and the arrival of a class free society. Democratic principles can be restored only in this latter phase of the dictatorship of the proletariat. Just like Stalin said that the State must be reinforced until it could be abandoned, democratic principles must be suspended before they can be reinstated in a truly democratic society free of class conflicts and exploitation. This is the ideological structure that was used by left wing intellectuals during the Cultural Revolution in the West.
